## Data in many forms

Statistics Canada disseminates data in a variety of forms. In addition to publications, both standard and special tabulations are offered. Data are available on the Internet, compact disc, diskette, computer printouts, microfiche and microfilm, and magnetic tape. Maps and other geographic reference materials are available for some types of data. Direct online access to aggregated information is possible through CANSIM, Statistics Canada's machine-readable database and retrieval system.

## How to obtain more information

Inquiries about this publication and related statistics or services should be directed to: Productivity Section, Input-Output Division, Statistics Canada, Ottawa, Ontario, K1A 0T6 (telephone (613) 951-3654) or to the Statistics Canada Regional Reference Centre in:

|          |                |           |                |

## Note of appreciation

*Canada owes the success of its statistical system to a long-standing co-operation involving Statistics Canada, the citizens of Canada, its businesses, governments and other institutions. Accurate and timely statistical information could not be produced without their continued co-operation and goodwill.*

## Symbols

The following standard symbols are used in Statistics Canada publications:

- .. figures not available.
- ... figures not appropriate or not applicable.
- nil or zero.
- amount too small to be expressed.
- P preliminary figures.
- r revised figures.
- x confidential to meet secrecy requirements of the Statistics Act.

## Contributors

This publication was produced under the direction of Kishori Lal, Director General, Systems of National Accounts and René Durand, Assistant Director, Input-Output Division.

**Tables, Graphs and Composition:** N. Richer, S. Zoschke

**Data Analysis and Development and Processing:** A. Baldwin, S. Burrows, J.-P. Maynard, M. Mirotschie, P. Mercier, A. Picard, S. Zoschke

The paper used in this publication meets the minimum requirements of American National Standard for Information Sciences - Permanence of Paper for Printed Library Materials, ANSI Z39.48 - 1984.

# The System of National Accounts

---

In Canada, the National Accounts have been developed since the close of the Second World War in a series of publications relating to their constituent parts. These have now reached a stage of evolution where they can be termed a "System of National Accounts". For purposes of identification, all publications (containing tables of statistics, descriptions of conceptual frameworks and descriptions of sources and methods) which make up this System carry the term "System of National Accounts" as a general title.

The System of National Accounts in Canada consists of several parts. The annual and quarterly Income and Expenditure Accounts (included with Catalogue Nos. carrying the prefix 13) were, historically speaking, the first set of statistics to be referred to with the title "National Accounts" (National Accounts, Income and Expenditure). The Balance of International Payments data (Catalogue Nos. with prefix 67), are also part of the System of National Accounts and they, in fact, pre-date the Income and Expenditure Accounts.

Greatly expanded structural detail on industries and on goods and services is portrayed in the Input-Output Tables of the System (Catalogue Nos. with prefix 15). The Catalogue Nos. carrying the prefix 15 also provide measures of the contribution of each industry to total Gross Domestic Product at factor cost as well as Productivity Measures.

Both the Input-Output tables and estimates of Gross Domestic Product by industry use the establishment as the primary unit of industrial production. Measures of financial transactions are provided by the Financial Flow Accounts (Catalogue Nos. with prefix 13). Types of lenders and financial instruments are the primary detail in these statistics and the legal entity is the main unit of classification of transactors. Balance sheets of outstanding assets and liabilities are published annually.

The System of National Accounts provides an overall conceptually integrated framework in which the various parts can be considered as interrelated sub-systems. At present, direct comparisons amongst those parts which use the establishment as the basic unit and those which use the legal entity can be carried out only at highly aggregated levels of data. However, Statistics Canada is continuing research on enterprise-company-establishment relationships; it may eventually be feasible to reclassify the data which are on one basis (say the establishment basis) to correspond to the units employed on another (the company or the enterprise basis).

In its broad outline, the Canadian System of National Accounts bears a close relationship to the international standard as described in the United Nations publication: *A System of National Accounts* (Studies in Methods, Series F, No. 2 Rev. 3, Statistical Office, Department of Economic and Social Affairs, United Nations, New York, 1968).

# Introduction

As in previous ones, this issue of *Aggregate Productivity Measures* introduces a number of changes to the presentation of the estimates. The multifactor productivity indices based on gross output are now presented with aggregate measures of inputs and outputs from our KLEMS data base which was described in the 1992 issue of this catalogue<sup>1</sup>. The capital, labour, energy, materials and services input indices together with the index of output are now presented in lieu of the corresponding partial productivity estimates as in the previous issue. All these indices are chained Törnqvist indices but other indices (Paasche, Laspeyres and Fisher Ideal) are available on request. These changes should be more useful to our readers as the KLEMS database may be used to compute partial productivity indices, if needed, as well as other indicators.

At the aggregate business sector level and for total manufacturing, productivity estimates are now presented in both rates of change and index levels, rather than rates of change only in order to facilitate the comparison with disaggregated industry indices. The expression net-gross output which was a short form used for gross output net of intra-industry sales has been suppressed and replaced everywhere by the complete expression. In the tables, the corresponding productivity indices are now more simply called intra-industrial to distinguish them from the industrial and interindustrial indices.

The most conspicuous change to the presentation, however, pertains to the introduction of new productivity estimates associated with final demand categories of expenditure. Previously, we presented the interindustry multifactor productivity indices that may be associated with either industries' gross output or with their final

sales to all final demand users. Re-weighting these commodity bundle indices according to the basket of goods purchased in each category of final demand provides an alternative interesting way of looking at productivity results. One may, for instance, compare the productivity growth generated in the Canadian economy by the industrial activities that support consumer durable goods as opposed to the efficiency gains generated by the activities supporting government purchases of goods and services. One may also proceed with a detailed analysis of productivity gains associated with our exports of these bundles bringing us one step forward in the analysis of competitiveness. For convenience, final demand has been broken down into 11 categories although results are available on request for the 128 categories included in the Input-Output Tables. Our highlights section briefly describes the movement of these new indices.

New capital stock data based on the 1980 SIC have been used to produce the revised estimates going back to 1961. These new capital data now permit the breakdown of the business sector into 122 industries rather than the 111 industries of the previous classification. The use of new capital stock data has made possible the introduction of estimates for Postal Services and Other Utilities within the business sector. The revised industrial classification used for the Multifactor Productivity Accounts is closer to that of the Input-Output Accounts.

Only Laundries & Cleaners (L code 151) and Other Personal Services (L code 152) are still excluded from the business sector estimates for lack of capital data. These industries account for only a small part of business sector output. Their aggregate gives the Personal & Household industry (M medium level code 46). Thus, all M level industries are now covered with the exception of M code 46. Since the excluded industries have only a minor impact on Community, Personal and Business Services industries our productivity indices cover virtually the S small level

1. See Johnson, J., "A KLEMS Database: Describing the Input Structure of Canadian Industry", in *Aggregate Productivity Measures*, 1992, Catalogue No. 15-204E, pp. 19-32.

of aggregation. Our concordance Tables in Appendix 3 have been revised to reflect these changes.

Another important change is related to the estimation of hours worked. Hours worked have been disaggregated to the input-output L link level code comprising 154 business industries with the exception of Government Royalties on Natural Resources and Owners Occupied Dwellings. Labour productivity and related variables estimates for the L level codes are available on request.

Tables comparing intra-industry productivity indices of manufacturing industries for Canada and United-States included in the Highlights of

the previous issue will now be regularly included in the Section titled Miscellaneous Tables. This Section will also include a table reporting the new productivity estimates by final demand categories and a table disaggregating the productivity estimates of the export category into 35 commodity groupings.

Multifactor productivity, labour productivity and related data now incorporate revisions due to the completion of 1991 final and 1992 preliminary input-output benchmark tables, as well as consequent revisions to 1991-1994 compensation and real GDP data. The KLEMS database introduced in the 1992 issue of this publication has also been updated and is now available to users.

#### **FOR FURTHER READING**

##### **Selected publications from Statistics Canada**

The labour and multifactor productivity indexes presented in this publication are obtained mainly from a set of integrated industry and commodity statistics within the System of National Accounts (SNA). The integration ensures consistency of definition over time and across industry and commodity classifications and the information may therefore differ from other Statistics Canada data. Publications with a catalogue number prefix 15 contain SNA integrated data and are available under the following titles:

- Gross Domestic Product by Industry, Cat. No. 15-001.
- The Input-Output Structure of the Canadian Economy, Cat. No. 15-201.
- The Input-Output Structure of the Canadian Economy in Constant Prices, Cat. No. 15-202.
- The Input-Output Structure of the Canadian Economy, 1961-81, Cat. No. 15-510, occasional.
- The Input-Output Structure of the Canadian Economy in Constant Prices, 1961-81, Cat. No. 15-511, occasional.

# Highlights

## In Brief

- In 1994, Canadian businesses registered their best productivity performance in 10 years. Modest increases in wages and business restructuring efforts contributed to the second consecutive annual decrease in unit labour cost.
- Productivity grew on average at the same pace in Canada as in the United States between 1991 and 1994. However, much smaller increases in Canadian wages meant production costs grew more slowly in Canada than they did in the United States. This improvement in relative prices, combined with the decline in value of the Canadian dollar, helped maintain the expansion of Canadian exports to the United States that started in 1992.
- A trend comparison has revealed that American manufacturers have been outperforming Canadian manufacturers in multifactor productivity since 1985. An analysis of 15 comparable manufacturing industries shows that the gap is essentially due to the machinery, electrical and electronic products industries, which grew much faster in the United States than in Canada.

## 1 - Productivity in Canada

### 1.1 - Strong recovery in productivity in 1994

In 1994, Canadian businesses registered their best productivity<sup>1</sup> performance in 10 years. Modest wage increases and business restructuring efforts contributed to the second consecutive annual decrease in unit labour cost.

1. Unless otherwise stated, the term «productivity» used in this publication refers to multifactor productivity measures based upon the value-added concept.

Despite 1994's productivity growth, the productivity index has still not regained its 1989 level. Not surprisingly, per capita Gross Domestic Product (GDP) in 1994 remained 1.1% below its 1989 level.

Figure 1

Productivity and Real GDP per capita are still below the level reached in 1989

### 1.2 - Productivity growth is less impressive than what was observed after the 1982 recession

Canadian business's real GDP rose by 5.5% in 1994, finally exceeding the 1989 peak. By comparison, after the 1982 recession, production returned to its 1981 pre-recession peak in just three years. Thus, the latest period of contraction and recovery was more prolonged than that of the decade before.

As well, productivity growth was weaker after the latest recession. In 1993 and 1994, the first two years of significant recovery, productivity increased 0.9% and 2.5%, compared with the 4.0% and 3.9% registered in 1983 and 1984, the comparable phase in the business cycle.

**Figure 2**

**The business sector's current productivity growth is less impressive than during the post 1982 recovery**

### **1.3 - Tighter reins on labour and modernization of equipment are partly responsible for slower productivity growth**

The 1990-1992 recession was more protracted than the short, sharp recession of 1982. This forced Canadian businesses to trim their payrolls in response to decreased demand. The cumulative number of person-years lost during the latest recession was approximately two times greater than in 1982, although the peak-to-trough fall in real GDP was farther in 1982.

When this recovery began, businesses were forced to expand hours worked and hire new employees more quickly than after the 1982 recession. At that time, employers kept a greater proportion of their employees on the payroll, so when recovery came, less hiring was needed. The increase in hours worked and hirings that occurred in 1993 and 1994 partly offset the cyclical productivity gains usually registered at this stage of the recovery. The fact that labour productivity increased by 1.2% over the 1990-1992 recession, while it dropped by 0.8% in 1982, supports this interpretation.

### **Cyclical pattern of productivity measures**

When businesses hear a sudden call to boost output, there is often a lag due to high hiring costs and the time it takes to buy and install new machinery and equipment. This time lag can be seen in cyclical fluctuations in productivity.

During a recession, productivity measures usually decrease or increase only slightly compared with their usual performance. Then, when recovery begins, they normally increase at a faster pace. It is important to consider these characteristics when interpreting the actual Canadian productivity performance.

Further, businesses modernized their production equipment to remain competitive to a greater degree than they did in 1982. Net investment in machinery and equipment was stronger during the latest recession and recovery than during the previous one. In the short run, however, modernization generally causes adjustments and training for labour which can delay productivity gains.

### **1.4 - Canadian manufacturers: The largest contributor**

In 1994, as in 1993, Canadian manufacturers made the greatest contribution to the productivity gains in the business sector. The productivity index of manufacturers increased 6.1% in 1994, bringing it closer to its 1985 peak. Manufacturers, like the entire business sector, registered lower productivity growth after the 1990-1992 recession than they did after the 1982 recession.

The labour index, though only a partial measure of productivity, is the best tool for a more detailed analysis, since multifactor productivity estimates for 1994 are not available by industry. Labour productivity grew strongly in 1994 in the manufacturing sector, and in the agricultural, communication, retail trade, and wholesale trade industries. However, labour productivity decreased for a third consecutive year in the construction, commercial, business and personal services industries.

**Figure 3**

**Productivity in the manufacturing sector posted its' best performance since 1984**

### 1.5 - Unit labour cost decreases for a second consecutive year

For the second consecutive year, Canadian businesses registered a drop in unit labour cost. The 0.7% drop in 1994 followed a 1.0% decline in 1993. These two years of decline stopped a trend of steadily rising unit labour costs since 1962. This decrease enabled Canadian businesses to limit the growth in their production unit cost, or price per unit produced, to 1.4% in 1994, and to increase their profits.

**Figure 4**

**Unit labour cost continued to decline in 1994 despite increased hourly compensation in the business sector**

In 1994, unit labour cost decreased both in the goods and services sectors. The most important decreases were observed in wholesale trade

(-4.9%), communication (-4.2%), agriculture (-2.9%), retail trade (-1.8%), manufacturing (-1.3%) and transportation and storage (-0.5%).

### 1.6 - Compensation per hour increased slightly in 1994

The hourly compensation paid to workers in the business sector rose 1.5% in 1994. This was greater than the previous year's rise, but was still the second-lowest increase in hourly compensation since 1947, the earliest year for which this measure is available. The main causes of these small rises are the modest increases allowed by collective agreements and an excess supply of labour.

Structural changes in the economy, which have shifted the employment distribution by industry, have also contributed to a slowdown in the growth of the gross payroll indicator. Since 1989, the relative importance of the service sector, where the average salary is lower than in the goods-producing sector, has increased. The numbers of hours worked in the service sector increased 4.6% from 1989 to 1994, while it decreased 7.7% in the goods-producing sector.

## 2 - Productivity by final demand categories

### 2.1 - Overview

As mentioned in the introduction of this publication, we introduce this year, for the first time, productivity gain estimates associated with final demand users' expenditures. These estimates require a brief explanation.

Business firms deliver commodities to final users-households, investors, governments and non-residents. Each of these agents has substantially different expenditure structures. But productivity gains made by firms also vary substantially from one commodity produced to another, as shown by the inter-industry multi-factor productivity indexes. Hence, aggregate productivity, at the business sector level, depends on the relative growth of final users' demand.

## 2.2 - Business investments come first

Figure 5 shows the business sector's productivity growth according to its deliveries to four groupings of final demand users: household expenditure; business investment, including changes in inventories; government expenditures on goods and services, including government investment; and exports.

Figure 5

### Productivity growth by final demand category

The business sector's largest productivity gains were in the production of business investment goods. Productivity gains on consumer expenditures ranked last. However, when final demand uses are broken down into the 11 categories shown in the Miscellaneous Tables Section, consumer durables and investments in machinery and equipment generated the greatest productivity gains. Productivity gains in household services were the weakest of all components of final demand, lowering the aggregate gains in the household expenditures category.

Productivity gains in exports were not much higher than the average gains of the business sector. However, Canadian exports are extremely diversified, and the average productivity gains shown in Figure 5 hide wide variations in individual categories. Table 1 illustrates that diversity.

Communications services posted the greatest productivity gains. However, these gains contributed little to productivity growth across the sector, because communications services repre-

sents such a tiny share of exports. In fact, the largest contributor to aggregate export productivity growth was transportation equipment followed by sawmill and other wood products.

## 3 - Productivity comparisons between Canada and the United States<sup>2</sup>

One could hardly talk about Canadian economic performance with respect to productivity growth and, in particular, of our export-related productivity, without comparing it with that of the United States, our major trading partner. In the eighties, our exchanges of goods and services with this country intensified so that they now amount to close to 80% of all of our exports.

### 3.1 - Canadian business performance continued to improve in 1994

In 1994, Canadian businesses recorded their best productivity gains in 10 years. Productivity grew by 2.5% in Canada, compared with 0.7% in the United States. As is also true for output and hours worked, a trend analysis shows that the cyclical pattern of the productivity index had more amplitude in Canada than in the United States. Despite these greater fluctuations, Canadian business productivity grew on average at the same pace as U.S. productivity between 1982 and 1994, and in fact since 1961. This indicates that the relative position of Canada in comparison with the United States did not change over the past three decades.

However, there are positive signs for Canada's competitive position in our hourly compensation and unit labour costs. Hourly compensation in the Canadian business sector grew by only 1.5% in 1994, compared with 2.7% in the United States. The combination of low wage increases and productivity improvement caused a second consecutive decrease in unit labour costs for the Canadian business sector, a result not seen in 48 years. In the United States, unit labour costs rose 0.7% during the same period.

2. Productivity and related data from the United States used in this publication were released by the U.S. Bureau of Labor Statistics.

**Table 1 - Productivity gains of exports by commodity (1961-1992)**

| Commodities                                | Productivity gains         |                                   |
|--|----------------------------|-----------------------------------|
|  | Average annual<br>% change | Average relative<br>contribution* |
| Communication services                     | 3.29                       | 0.92                              |
| Textile products                           | 3.21                       | 1.23                              |
| Lumber, sawmill, other wood products       | 2.75                       | 14.35                             |
| Forestry products                          | 2.66                       | 0.74                              |
| Autos, trucks, other transp. equipment     | 2.61                       | 29.17                             |
| Transportation margins                     | 2.59                       | 13.34                             |
| Electrical & communications products       | 2.53                       | 4.92                              |
| Other agricultural products                | 2.42                       | 4.15                              |
| Grains                                     | 2.28                       | 11.67                             |
| Knitted products & clothing                | 2.26                       | 0.56                              |
| Rubber, leather, plastic fab.pro           | 2.09                       | 1.03                              |
| Miscellaneous manufactured products        | 1.91                       | 1.81                              |
| Wholesale margins                          | 1.89                       | 5.36                              |
| Fruit, vegetable, feed, misc.food products | 1.86                       | 2.45                              |
| Chemicals, chemical products               | 1.85                       | 4.77                              |

\* Average of the annual value share weighted productivity gains in proportion of total exports productivity gains

Figure 6

The relative position of Canadian businesses, in terms of productivity, did not change over the past three decades

Table 2 - Growth rates of business sector performance indicators for Canada and the United States

| Year | Multifactor productivity |      | Labour productivity |      | Hourly compensation |      | Unit labour cost |      | Canadian unit labour cost in U.S. \$ |
|------|--------------------------|------|---------------------|------|---------------------|------|------------------|------|--------------------------------------|
|      | Canada                   | U.S. | Canada              | U.S. | Canada              | U.S. | Canada           | U.S. |                                      |
| 1981 | 0.6                      | 0.3  | 2.1                 | 1.3  | 12.9                | 9.4  | 10.6             | 8.0  | 7.8                                  |
| 1982 | -4.3                     | -3.1 | -0.8                | 0.1  | 10.0                | 7.5  | 11.0             | 7.4  | 7.8                                  |
| 1983 | 3.9                      | 2.1  | 4.1                 | 2.3  | 4.9                 | 3.8  | 0.8              | 1.5  | 0.9                                  |
| 1984 | 4.0                      | 3.1  | 3.5                 | 2.4  | 5.1                 | 4.4  | 1.5              | 1.9  | -3.4                                 |
| 1985 | 1.0                      | 0.5  | 0.5                 | 1.4  | 3.8                 | 4.5  | 3.2              | 3.0  | -2.1                                 |
| 1986 | 1.0                      | 1.0  | 1.5                 | 2.1  | 4.8                 | 4.9  | 3.2              | 2.8  | 1.4                                  |
| 1987 | 1.0                      | 0.2  | 1.1                 | 1.0  | 5.9                 | 3.6  | 4.8              | 2.6  | 9.8                                  |
| 1988 | 0.0                      | 0.5  | 0.8                 | 1.0  | 6.3                 | 4.4  | 5.4              | 3.3  | 13.6                                 |
| 1989 | -0.5                     | -0.2 | 0.9                 | -0.7 | 6.6                 | 3.5  | 5.7              | 4.3  | 9.9                                  |
| 1990 | -3.4                     | -0.2 | -1.6                | 0.7  | 4.1                 | 5.7  | 5.8              | 5.0  | 7.3                                  |
| 1991 | -1.2                     | -1.0 | 1.1                 | 1.3  | 5.7                 | 4.8  | 4.6              | 3.5  | 6.5                                  |
| 1992 | 0.2                      | 1.4  | 1.6                 | 3.0  | 3.1                 | 5.1  | 1.4              | 2.1  | -3.9                                 |
| 1993 | 0.9                      | 0.5  | 1.1                 | 1.3  | 0.1                 | 3.4  | -1.0             | 2.0  | -7.2                                 |
| 1994 | 2.5                      | 0.8  | 2.2                 | 2.1  | 1.5                 | 2.7  | -0.7             | 0.7  | -6.2                                 |

When currency exchange rates are taken into account, unit labour costs in the Canadian business sector look even better. Canadian unit labour costs measured in U.S. dollars fell by 6.2% in 1994. Since U.S. unit labour costs continued to increase in 1994, there was a gap of 7.0% between the Canadian and U.S. business sector. This improvement in relative prices in Canada contributed to the recent surge of Canadian real exports to the United States. The ratio of Canadian real exports to the U.S. in proportion to real U.S. GDP has increased significantly from 2.2% in 1991 to 3.0% in 1994 (see figure 7) so that the increase in these exports during this period was not just a reflection of growth in the American economy.

**Figure 7**

**Canadian exports to the U.S. are sensitive to changes in relative prices**

### 3.2 - Unit labour costs in manufacturing drop more in United States

Manufactured goods represent more than 75% of all Canadian exports including services to the United States. So it is particularly interesting to examine the manufacturing industries in each country in more detail.

Aggregate measures of productivity in the Canadian and U.S. manufacturing sectors show that, before exchange rates are taken into account, the Canadian sector lost some competitive ground in 1994 (see table 3). Canadian manufacturing wages increased by 2.9%, while U.S. wages rose only by 1.6% in 1994. Since labour productivity grew similarly, manufacturing unit labour costs dropped by 1.3% in Canada, compared with 2.3% in the United States.

As in the entire business sector, when the 1994 unit labour costs are corrected for the exchange rate, Canadian manufacturers enjoyed an attractive competitive position for a third consecutive year (see figure 8). Canadian unit labour costs measured in U.S. dollars fell by 6.8% in 1994. This drop leaves a gap of 4.5% in favour of Canadian manufacturers, lower than in the two previous years.

**Table 3 - Growth rates of manufacturing industries performance indicators for Canada and the United States**

| Year | Labour productivity |      | Hourly compensation |      | Unit labour cost |      | Canadian unit labour cost in U.S. \$. |
|------|---------------------|------|---------------------|------|------------------|------|---------------------------------------|
|      | Canada              | U.S. | Canada              | U.S. | Canada           | U.S. |                                       |
| 1981 | 4.9                 | 3.6  | 15.1                | 9.8  | 9.7              | 6.1  | 7.0                                   |
| 1982 | -4.5                | 4.0  | 10.6                | 9.3  | 15.8             | 5.2  | 12.6                                  |
| 1983 | 7.3                 | 2.2  | 6.1                 | 2.7  | -1.1             | 0.4  | -1.0                                  |
| 1984 | 8.5                 | 1.3  | 4.7                 | 3.2  | -3.4             | 2.0  | -8.1                                  |

**Figure 8**

**The competitiveness of Canadian manufacturers continues to benefit from the devaluation of the dollar**

### 3.3 - Manufacturing productivity growth in Canada and the United States

Manufacturing productivity, based upon intra-industry indexes, are comparable for 15 industry groups up to 1992 and the whole Canadian and U.S. manufacturing sector up to 1993.<sup>3</sup> A detailed analysis of productivity indexes for the 15 industry groups points out the best-performing industries in the two countries.

Between 1961 and 1993, productivity growth was greater in U.S. manufacturing than in Canada's. The U.S. manufacturing sector had a compound annual rate of growth of 1.3%, while Canadian manufacturing saw annual growth of 0.9%. The cumulative effect of this 0.4% difference over more than 30 years could have had

significant impact on the two countries' economic growth.

Between 1961 and 1985 the Canadian and U.S. multifactor productivity indexes were never greater than 5.0 points apart, with an average differential of 1.4. Figure 9 shows that during this period, the indexes grew at much the same rate in each country (1.3% in Canada and 1.4% in the United States).

However, after 1985 Canadian manufacturing lost ground. The difference between the Canadian and U.S. indexes was always greater than 5.0 points, with an average differential of 12.6 points. Canadian manufacturing's productivity declined an average 0.3% each year, while the U.S. index continued to rise at an average 1.0% per annum. The decline in Canadian manufacturing productivity after 1985 explains almost entirely the lower growth rate observed over the entire 1961-1993 period. However, the gap in the manufacturing indices grew from 1985 to 1992, but was slightly narrower in 1993.

3. Starting with section 3.3, "productivity" refers to MFP based on the concept of intra-industry indexes. This measure is used because this is the only official MFP measure available for U.S. manufacturing. In order to make comparisons between Canada and the U.S., the Canadian measures must be recalculated based upon intra-industry indexes. For the purposes of comparability, the forestry industry had to be added to total manufacturing in Canada in order to be consistent with the U.S. definition. The 15 comparable industries represent approximately 90% of manufacturing output in both countries.

**Figure 9**

**After deteriorating from 1985 to 1992, the productivity gap between the Canadian and American manufacturers slightly improved in 1993**

### 3.4 - Relative performance of individual industries

Between 1961 and 1985, Canadian manufacturers had higher rates of productivity growth in 10 of 15 industries, but after that year U.S. manufacturers enjoyed higher productivity growth in all 15 industries.

In the 10 industries where Canada had higher rates of growth during the first period, the gap between Canada and the United States was 0.6% on average. But from 1985 to 1992 the United States was ahead by an average gap of 1.3%. As well, the two largest gaps in Canada's favour between 1961 and 1985 were in printing and publishing (0.9%) and wood products (0.8%). After 1985, the two largest gaps in favour of the U.S. are much more significant. They are in machinery, electrical and electronic products (3.2%), and paper and allied products (2.1%).

When the entire period from 1961 to 1992 is considered as a single unit, the annual growth rate of productivity in 7 of the 15 industries in this comparison was greater in Canada. The United States had higher growth rates in 6 of the remaining industries, while growth was equal in leather and allied products and textile and textile products. Despite this split U.S. manufactur-

ers realized higher overall productivity gains in the manufacturing sector compared with Canadian manufacturers.

The difference in productivity growth rates over the entire period from 1961 to 1992 can largely be attributed to the superior performance of the machinery and electrical and electronic products industries<sup>4</sup> in the United States. During this period, this industry was relatively more important in the United States than in Canada, accounting for 13.5% of manufacturing gross output compared with 9.1% in Canada. Second, productivity in this industry grew over the period at 2.6% per year in the United States, compared with 1.2% in Canada. Productivity in this industry led by a narrow margin in the U.S. in the 1960s and 1970s, and then pulled farther ahead in the 1980s. In short, this industry had a much more important role in the manufacturing industry in the United States, and enjoyed much greater productivity growth.

4. This has to be qualified by the difficulties of deflating computer equipment which could potentially introduce a bias in the results. In top of computer equipment, this industry includes a wide variety of products such as agricultural implements and telecommunications equipment.

**Table 4 - Productivity growth rates between Canada and the United States for comparable manufacturing industries**

---

Figures 10 and 11 also shed some light on the contribution<sup>5</sup> of each industry to the growth in productivity in all manufacturing industries. In the United States, machinery, electrical and electronic products had the greatest influence on the growth rate of productivity for the entire manufacturing industry. Its contribution is almost four times as large as that of the food and bever-

age industry, the next most significant contributor. In Canada, the contributions of each industry are more evenly distributed. In fact, the three largest contributors to Canadian manufacturing productivity growth are almost equal to the single largest U.S. contributor.

---

5. The contribution of each industry is calculated as the nominal value of gross output net of intra-industry sales of that industry divided by the nominal value of gross output net of intra-industry sales for the entire manufacturing sector, then multiplied by the growth rate of productivity for that industry from 1961 to 1992.

## Methodology used to Produce Advance Estimates of Multifactor Productivity Indexes for the Canadian Aggregate Business Sector

by  
Mesfin Mirotchie<sup>1</sup>

### 1 - Introduction

The purpose of this paper is to explain the methodology used to compute advance estimates of the Canadian business sector aggregate multifactor productivity (MFP) indexes for recent past years<sup>2</sup>. The methodology uses aggregate proxy variables with incomplete information. The paper discusses how the proxies are calculated and how well they approximate the actual variables over the historical record. The discussion is organised under three sections. Section two identifies multifactor productivity variables, two equations - one that is used to compute historical MFP indexes with complete information and one that is used to generate advance MFP estimates with proxy variables - and indicates the reasons for implementing the proxy approach. Section three explains the compilation of the proxy variables with an emphasis on three points: (a) data sources and adjustments to the data, (b) the mechanics of the estimation of the past and extrapolation of advance estimates, and (c) the tabular and graphical analysis of the results generated with the proxy model. The last section demonstrates how the projected estimates are applied to compute advance aggregate MFP indexes for the most recent years.

1. The author wishes to thank René Durand for his valuable comments at various stages of this paper and J.P. Maynard for his inputs at the early stages of the paper. However, the author assumes full responsibility for the paper.
2. The term "advance" is used in this paper to describe the projection of MFP indexes over the recent past (but not the future) years for which complete information is not available. For example, the 1992 input-output tables which contain complete historical information are published in 1995 with a three-year lag. Therefore, the advance estimation with proxies is done in 1995 for the two recent past years, namely, 1993 and 1994.

### 2 - The Need for Advance Estimation

The need for advance estimation by proxies is predicated primarily by a necessity to produce timely multifactor productivity estimates. This by itself is the outcome of the unavailability of timely detailed economic data for the most recent past years for which the productivity estimates are required.

At the aggregate business sector level, multifactor productivity growth,  $\tau$ , is computed as the difference between the rate of growth in real value-added (or real GDP),  $\dot{y}$ , and the weighted rates of growth of labour,  $\dot{L}$ , and capital,  $\dot{K}$ , inputs by industry<sup>3</sup>. In a mathematical short hand, the relationship is often expressed as:

$$\tau = \dot{y} - (\omega_L^T \dot{L} + \omega_K^T \dot{K}) \quad (1)$$

where  $\omega_L$  and  $\omega_K$  are vectors of the cost shares of  $L$  and  $K$  inputs, respectively, valued in current prices<sup>4</sup>. Labour input is measured in terms of hours worked and capital is measured in terms of the real net end-of-previous-year capital stock.

Over the historical record, the variables  $\dot{y}$ ,  $\omega_L^T \dot{L}$  and  $\omega_K^T \dot{K}$  are computed as chained Törnqvist<sup>5</sup> indices from detailed information at the disaggregated industry level. Such information is not

3. At its most detailed level of the MFP estimation, the aggregate Canadian business sector contains 122 industries.
4. Note that vectors and matrices are bold. The superscript T indicates the transpose of matrices and vectors and the dot symbol over the variables indicates temporal growth rates.
5. The chained Törnqvist index is a discrete time approximation in which logarithmic changes are weighted by arithmetic averages of the shares over the current and the previous year.

available for the few most recent past years. Scalar proxies,  $y$ ,  $L$  and  $K$ , are therefore needed for the indexes of aggregate real GDP and labour and capital inputs, respectively. The corresponding aggregate factor shares,  $s_L$  and  $s_K$ , are available for the most recent past years and do not need to be approximated. The approximation equation is given by:

$$\tau = \dot{y} - (s_L \dot{L} + s_K \dot{K}) \quad (2)$$

where the variables are as defined previously.

### 3 - Compilation and Estimation of the Proxies

The Productivity Accounts are closely linked to the Input-Output Accounts, which, generally, are produced with a lag of about three years relative to the current calendar year. The Productivity accounts also rely on detailed estimates of hours worked and capital stock data reconciled with the concepts and methods of National Accounts. In particular, the data are classified uniformly according to the current industrial classification while some source data are not. In addition, the estimates are produced according to the sectoral breakdown of the accounts into business and non business activities. Since the Productivity Accounts pertain only to the business sector, hours worked and capital stock data have to be estimated for that sector before productivity estimates are derived.

These adjustments can not be made for the recent past years since the adjustments are based on reconciled information contained in the input-output tables. Moreover, aggregate capital stock estimates are produced with the Törnqvist index formula which makes use of detailed industry weights (chained over time) that are not available for the recent past years. The unavailability of the requisite information necessitates the development of proxy capital stock data on the basis of (unchained) Laspeyres index formula by summing constant price estimates for each industry.

Both real and nominal GDP data are adjusted similarly. The data are further adjusted by excluding two industries: Royalties on Natural

Resources and Owner-Occupied Dwellings, since the two industries are excluded from the benchmark estimates of both labour and multi-factor productivity indexes [Table 1]. In addition, nominal GDP data at factor cost are adjusted by adding the value of Other Indirect Taxes which are considered to be part of the gross income accruing to capital. The adjusted nominal GDP is used to compute the factor income shares for labour and capital inputs, whereas, the adjusted real GDP is the proxy used to project the Törnqvist index of real GDP. The basic data for this variable are derived by Laspeyres index formula.

Finally, the labour hours worked data are summed over several industries without adjusting for labour quality differences<sup>6</sup>.

The data for the proxy variables are derived from a combination of two broadly defined sources. First, aggregate proxy (nominal and real) GDP data are compiled from the Canadian System of National Accounts, and, second, data on aggregate proxy variables for capital stock and labour are compiled from the subject matter divisions within Statistics Canada. Once the data are compiled, they undergo several adjustments that are summarized in Table 1.

Capital stock data come from Investment and Capital Stock (ICS) Division. The aggregate business sector nominal GDP estimates in current prices and the associated aggregate factor income shares are taken from the *Income and Expenditure Accounts* (Catalogue 13-201 Annual) from the National Accounts and Environment (NAE) Division. The real GDP estimates are taken from the monthly estimates of gross domestic product at factor cost published by the Industry Measures and Analysis (IMA) Division in the *Gross Domestic Product by Industry*, (Catalogue 15-001 Monthly). Labour data are taken from the Labour Productivity Accounts of the Input-Output Division. At the aggregate business sector level, hours worked in the Labour Productivity Accounts consist of hours worked

6. Normally, over the historical benchmark years, differences in labour quality are adjusted by weighting hours worked by the relative proportions of labour compensation as in equation (1).

**Table 1 - Summary of Proxy Data Sources and Adjustments**

| Variable                    | Source                | Adjustments   |
|-----------------------------|-----------------------|---|
| Capital Stock               | ICS Division          | Exclude Non-business Sector Data                                |

| Labour (Total Hours Worked) | Productivity Accounts | No Adjustments  |

by the civilian population regularly surveyed through the *Labour Force Survey* (Catalogue 71-001 Monthly).

### 3.1 - Graphical Analysis of the Actual and Proxy Variables

A graphical evaluation of the proxy variables vis-à-vis the actual variables helps one to see how good are the proxies as substitutes for the actual variables. Figures 1 to 3 compare the similarities and differences between the actual and proxy data series. The proxy data series span a total of 33 years from 1962-1994, whereas, the actual data series go only through to 1992. As such, the comparison of the series is meaningful only within the time periods covered by the actual data series. The proxies reflect the likely direction of growth of the actual historical series extended over the most recent past years.

Figure 1 compares historical growth rates in actual and proxy real GDP values. Figure 2 exhibits growth rates of proxy hours worked with the actual total hours worked over the historical time period. Similarly, Figure 3 contrasts historical rates of growth in the proxy aggregate capital stock with the growth rates of actual capital stock series. As can be seen, the first two figures clearly demonstrate that the differences between the proxy and the actual variables are minimal and the proxies are likely to perform satisfactorily as the projectors of the actual variables.

However, the same level of confidence may not be attributed to the capital proxy variable. As depicted in Figure 3, for the most part, the proxy capital variable appears to underestimate the rate of growth in the realised capital stock variable over the historical period. To the extent that

this is a systematic pattern, it may be corrected as will be shown later. But one thing to note is that the temporal movement of the actual and proxy capital variables is in the same direction although the growth rates do not appear to be as highly transparent as in the two previous cases. Unlike the series for the other two variables, however, the turning points and, at times, the direction of change of the capital stock series do not appear as tightly synchronised over the historical period.

The projection model which is discussed next will indicate the level of bias and the degree of precision with which each of the proxy variable approximates the corresponding actual variable. The precision cannot be improved but the bias may be eliminated through a linear correction using the results of the simple linear regression.

### 3.2 - Econometric Estimation of the Precision and Bias of the Proxies

Once the task of collecting and adjusting the data for the proxy variables is completed, the next step is to make advance estimates based on the proxies. For this, an econometric technique is used to estimate the following equation with the proxies.

$$A_t = \alpha_0 + \alpha_1 P_t + \beta_1 d_1 + \beta_2 d_2 + u_t \quad (3)$$

where  $A_t$  and  $P_t$  represent any one of the actual and corresponding proxy variables, receptively, for year  $t$ , the  $d$ 's are dummy variables taking successively a value of one for projection years 1 and 2 and zero otherwise, and  $u_t$  is the regression residual; and  $\alpha_0$  and  $\alpha_1$  are the intercept and slope estimators, respectively. The  $\beta$ 's are the dummy variable parameters providing the pro-

Figure 1 - Comparison of Proxy and Actual Measures of GDP Growth Rates

Figure 2 - Comparison of Proxy and Actual Labour Hours Worked Growth Rates

Figure 3 - Comparison of Proxy and Actual Capital Stock Growth Rates

jected growth rates of the actual variables. That is, setting  $A_t$  equal to zero over the recent years and solving for the coefficients of the dummy variables produces the projected growth rates.

The estimation of equation (3) complements the graphical analysis of the previous section and generates quantitative tools to assess how well the proxies approximate the actual variables. The assessment of the econometric results is important for two reasons. First, it will indicate the accuracy of the proxies which is transparent to the reliability of the advance estimates. Second, the proxies may have a systematic bias that must be corrected leaving only the non-systematic component of the error term. Both of the above reasons for the assessment of the econometric results are illustrated in Figure 4.

Proxies that do not contain a systematic bias will generate a 45 degree line with a perfect fit. Even if the proxies contain a systematic bias that is non-degrading to the estimated parameters, the regression line will still be close to the perfect proxy line indicated by  $A_t = 0 + P_t$ . However, if there is a systematic and degrading bias, the regression line lies further away from the perfect fit line and the gap between the two lines depends on the level of bias.

**Figure 4 - A conceptual illustration of accuracy and bias in proxy variables**

Unless corrected, the bias can damage the ability of the proxies to generate reliable advance estimates. Because of the possibility of the presence of such bias, the performance of the proxies is scrutinised over the entire historical period (1962-1994 in the present case) using Theil's linear correction model<sup>7</sup>. The model is constructed in such a way that logarithmic changes in the actual variables,  $A$ , are regressed on the logarithmic changes in the corresponding proxies,  $P$ . The model generates key statistical parameters of interest including an intercept, a slope, standard errors of the estimated parameters, and corrected multiple determination coefficient,  $\bar{R}^2$ .

The proxies are unbiased predictors of the actual variables if the estimated intercept and slope parameters are not statistically different from zero and one, respectively, as depicted by the 45° line on the above figure. Proxies are reliable indicators of the actual variables if the proportion of the variation in the actual variables explained by the variations in the proxies (i.e.,  $\bar{R}^2$ ) is close to 100%. Generally, however, econometric estimates show a departure from the line of perfect fit. For instance, if the actual variable is growing 90% as fast, on average, as the proxy, then the slope parameter of the regression line will be 0.9. The observed bias may be corrected by reducing the rate of growth of the proxy by 10%. The correction for the bias is made on both the slope and the intercept parameters. On the other hand, the precision of the parameters is determined by the relative size of the standard error corresponding to each parameter estimate and it cannot be improved.

In addition to the above actual and proxy variables, two dummy variables, one for each year for which realised data are not available for the Törnqvist variables, are added to the explanatory variables of the model.

#### 4 - Estimates and Forecasts of the Variables

The empirical results of the regression analysis, based on 33 time series observations from 1962-

7. Theil, H., *Applied Economic Forecasting*, Chicago: Rand McNally and Company, Amsterdam: North-Holland Publishing Company, 1966.

1994, are summarised in Table 2. Among other statistics of interest, the regression results consist of both historical and forecast growth rates for the three dependent variables, namely, real GDP, total hours worked, and net aggregate capital stock. The variables are expressed in logarithmic changes.

As can be seen from Table 2, the estimated model parameters meet almost all of the test conditions discussed previously. The intercept parameters are not significantly different from

values of the variables and their proxies. In these figures the pairs of observations are represented by spherical dots and the regression (fitted) results are indicated by a solid line.

The essential point to be noted from these figures is the movement of the observed (actual) series relative to the movement of the fitted proxy series. As the figures indicate, the fitted regression series are close to the 45° line and the observed series are narrowly dispersed around that line. Nevertheless, the dispersion of the

|                         | dummy <sub>1994</sub> | $\beta_2$            | 1.17                | 0.819     |                    | -0.50                    | 2.85  |

zero and the estimated slope parameters are not significantly different from unity except for the output variable at the 5% level of significance. Also, the models, especially for the real GDP and total hours worked, have a high  $\bar{R}^2$ ; thus, have a high goodness of fit. It can be concluded that the proxies are unbiased and fairly precise predictors of the actual variables; although a slight slope correction seems appropriate in the case of the capital stock. Also, as indicated by the size of the  $\bar{R}^2$  statistic, the amount of variation explained by the capital stock model is low relative to the other two models.

The scatter diagrams in figures 5 to 7 below further describe the relationship between the actual

observations around the regression line "drifts" away steadily in figures 6 and 7 relative to figure 5. This reflects the higher precision or  $\bar{R}^2$  of the regression for the real GDP variable, followed by hours worked and net aggregate capital stock variables.

#### 4.1 - Projections of the Aggregate MFP Indexes

The projected growth rate of the real gross domestic product of the business sector for 1993 and 1994 are respectively of 2.92% and 4.97%.

These rates of growth in real GDP are closely related to the changes in the projected growth

**Figure 5 - Observed and fitted real GDP growth rate series**

**Figure 7 - Observed and fitted capital stock growth rate series**

**Figure 6 - Observed and fitted labour hours worked growth rate series**

ship captured in equation (2) is applied with the projected variables. For example, for 1993, the combination of the projected rates of growth in real gross domestic product, total hours worked and capital stock with the labour share of 0.71 and the capital share of 0.29, the aggregate factor productivity estimate is:

$$\tau_{1993} = 2.92 - 0.71 \cdot 2.23 - 0.29 \cdot 1.93 = 0.79 \quad (4)$$

The above result in Equation (4) provides an advance estimate of 0.79% increase in the aggregate multifactor productivity of the Canadian business sector in 1993 relative to the 1992 production period. A similar calculation gives the projected productivity gain of 2.28% for 1994.

rates of labour and capital inputs. The projected rate of growth in the total hours worked are 2.23% and 3.37% in 1993 and 1994 respectively. The net capital stock is projected to increase at a rate of 1.93% and 1.17% over the same period.

The projected growth rates, are now available for the calculation of the aggregate multifactor productivity estimates. To do this, the relation-

## APPENDIX 1

### Basic Concepts and Methods

Ideally, a productivity index is one that takes into account all paid resources that are used as inputs into the production process. A comprehensive measure, such as this, is called a **total factor**, or, alternatively, a **multifactor** productivity index. This is the focus of Part 1 of this publication. Productivity indices that take into account only a subset of the inputs such as, for instance, labour productivity indices, are called **partial productivity indices**. Labour productivity indices are presented in Part 2 of this publication.

The labour productivity estimates have a longer history than the rather recent multifactor productivity estimates. Consequently, they were not derived as partial indices of the multifactor productivity indices and they thus require a separate methodological description.

In particular, the labour productivity indices are based on a Laspeyres measure of real gross domestic product by industry which is not used in the multifactor productivity accounts. Hence, this appendix presents separately the basic concepts and methods used in the labour and the multifactor productivity accounts.

The concept of productivity may refer to the entire Canadian economy and/or to various components of the economy. These components, in the Canadian System of National Accounts, are either sectors or industries. The productivity indices refer only to the productivity of the resources used by the business sector of the economy. In the Canadian System of National Accounts, the business sector "encompasses that group of transactors who produce goods and services for sale at a price which is calculated to cover costs and yield a profit..."<sup>1</sup>. An industry is defined, in the National Accounts, "as a group of operating units [establishments] engaged in

the same or similar kind(s) of economic activity, e.g., coal mines, clothing factories, department stores, laundries"<sup>2</sup>. Industries include both business and non business establishments but can be sectorised to include only business establishments. Both the labour and the multifactor productivity indices presented in this publication refer, either explicitly or implicitly, to business establishments only.

The productivity of the government sector can not be calculated at this time in the framework of the Canadian System of National Accounts. The output of non-business sector industries is difficult to measure because it is not normally sold on the market. This means that in general, output prices are not available for this sector. The conventional measure of real output for non-business sector industries is therefore constructed by deflating the value of output with input prices. By convention (for lack of a better alternative), this amounts to measure the real output of the government sector as being equal to its primary input use. As a consequence, the growth in output cannot diverge from the growth in inputs as required for a meaningful productivity measure<sup>3</sup>.

#### 1 - Labour Productivity and Unit Labour Costs

##### 1.1 - Labour Productivity

The labour productivity measure is **real GDP per hour worked**. This indicator is constructed as a ratio of real output to labour input, and is presented in index number form.

Although labour input is an important determinant in the level of output, it is not the only one.

1. Robert B. Crozier, *National Income and Expenditure Accounts, Volume 3, A Guide to the National Income and Expenditure Accounts, Definitions-Concepts-Sources-Methods* (catalogue 13-549, 1975, p. 101).

2. *The Input-Output Structure of the Canadian Economy, 1961-1981* (catalogue 15-510, p. 18).

3. Further detail on the industry coverage of the productivity measures in this publication can be found in Appendix 3.

Other inputs also contribute to the production process. Partial productivity indices that do not take these inputs explicitly into account are therefore subject to changes in these inputs as one of the component of the productivity ratio, namely the output level, is partly determined by these other inputs. Hence, a partial productivity index may rise through time either because these other inputs are used in larger quantity or because the efficiency of the production process improves or both. It follows that partial productivity indices such as the labour productivity indices are not precise indicators of overall productive efficiency.

## 1.2 - Output

The concept of output used in labour productivity measurement is the constant price Gross Domestic Product at factor cost by industry (excluding Government royalties on natural resources and rents of Owner-occupied dwellings). The output measures are calculated with 1961 prices for the period 1961 to 1971, with 1971 prices for the years 1971 to 1981, with 1981 prices for the years 1981 to 1986. Estimates in subsequent years are calculated with 1986 prices. These series were then rescaled to correspond to a 1986 reference year (i.e. 1986=100) for convenience, as 1986 is the base year currently in effect in the Canadian System of National Accounts. The rates of growth in the original series are not affected by the choice of reference year. A more complete description of the output measures is found in *The Input-Output Structure of the Canadian Economy 1961-1981* (Catalogue 15-510) and in *The Input-Output Structure of the Canadian Economy in Constant Prices, 1961-1981* (Catalogue 15-511).

## 1.3 - Labour Input

In principle, labour input should cover all labour services expended to produce a given output. This report presents one measure of labour services: the hours worked. This measure does not take into account the changing quality of labour input as is the case when measuring multifactor productivity. But the underlying estimates of persons at work and on-hours worked are the same in both set of productivity estimates. Thus, the aggregate labour inputs of

different classes of labour are obtained by adding the number of hours worked across classes.

**Persons at work** denote all paid and other-than-paid persons engaged in the production of output. Other-than-paid workers include self-employed workers and unpaid family workers.

**Hours worked** are the sum of hours worked spent at the place of employment by persons at work, and therefore differ from a measure of hours worked paid by excluding vacation time, holidays, time lost due to illness, accidents, etc.

## 1.4 - Labour Compensation

Labour compensation is a measure of the value of labour services engaged in the production process. It includes all payments in cash or in kind by domestic producers to persons at work as remuneration for work, including wages, salaries and supplementary labour income of paid workers, plus an imputed labour income for self-employed workers. Statistics on labour compensation reported here represent the most comprehensive labour cost data available for all industries at the present time since they include both cash payments and supplements and cover all remunerated persons at work.

The estimate of the value of labour services of self-employed persons is an imputed value. The imputation is based on the assumption that the value of an hour worked by a self-employed person is the same as the value of an hour worked by an average paid worker in the same industry. This assumption is based on the premise that labour services are contracted on a temporal basis, and a measure of labour compensation should not reflect returns on investment or risk taking. An adjustment is made in the case of self-employed persons such as doctors, dentists, lawyers, accountants and engineers. In these cases, the average earnings of paid workers in the same industry tend to be lower than the earnings of the self-employed workers. Although self-employed workers are in majority in the industry, the imputation of earnings for these workers at the average rate in the industry tends to underestimate the income of the self-employed. In this case, direct evi-

dence on average labour income of these workers is introduced.

Unpaid family workers, while not directly recompensed for their services, are not a free resource, and their contribution is reflected in the net income of the firm where they are employed. However, no labour income is imputed to unpaid family workers. There is no valid basis for measuring the value of their services, and it is judged that less error is generated by their exclusion from measures of labour compensation than by imputing labour income to them at the same rate as paid workers. The number of unpaid family workers is insignificant in most industries.

### 1.5 - Unit Labour Cost

Unit labour cost is the ratio of labour compensation to real GDP. It is a measure of the cost of labour per unit of real output. Unit labour cost can also be viewed as the ratio of average compensation to labour productivity; thus, unit labour cost will increase when average compen-

sation grows more rapidly than labour productivity.

### 1.6 - Absolute Values

All time series in this report are presented as indices taking a value of 100 in 1986. This form emphasizes relative change, as opposed to levels, as being important in the construction of productivity measures and related cost series. One can reconstruct the absolute values underlying the indices of hours worked, real gross domestic product and labour compensation. These absolute values are of some interest as they indicate the level of those series. Nevertheless, the growth rate of the series is the same whether it is calculated from the index or the absolute values.

Table 1 gives the absolute values underlying the indices for the year 1986. To calculate the absolute values corresponding to the published indices the following procedure can be followed:

$$\frac{\text{Index} \times 1986 \text{ value from Table 1}}{100}$$

**Table 1 - Absolute values of labour productivity and unit labour cost, 1986**

| Industry Title   | Real gross domestic product | Hours worked | Labour compensation |
|--|-----------------------------|--------------|---------------------|
|  | \$'000,000                  | 000,000      | \$'000,000          |
| Business sector industries   | 335,673                     | 15,320       | 225,279             |
| Business sector - excluding agricultural and related services industries | 324,616                     | 14,237       | 219,748             |
| Business sector - services   | 173,374                     | 9,015        | 126,419             |
| Business sector - goods  | 162,299                     | 6,305        | 98,859              |
| Agricultural and related services industries                             | 11,057                      | 1,082        | 5,531               |
| Manufacturing industries   | 86,789                      | 3,341        | 56,919              |
| Construction industries  | 28,082                      | 1,242        | 23,449              |
| Transportation and storage industries                                    | 20,254                      | 897          | 14,758              |
| Communication industries   | 13,248                      | 353          | 7,645               |
| Wholesale trade industries   | 23,312                      | 1,066        | 17,128              |
| Retail trade industries  | 28,269                      | 2,343        | 23,949              |
| Community, business and personal services industries                     | 52,119                      | 3,286        | 41,921              |

The measurement of employment, output, and the other series mentioned above are subject to some, usually indeterminate, margin of error. These errors usually have a larger impact on the level of the estimates than on their growth rates. While such statistical errors will also have some effect on measures of relative change, it can be expected that their effect will be more serious when comparisons of absolute levels are attempted.

## 2 - Multifactor productivity

### 2.1 - Multifactor Productivity in a Nutshell

Although the partial labour productivity indices described above are appropriate for many analytical uses, they do not describe exhaustively the sources of economic growth. This is the case because measured changes in output per unit of labour input are not necessarily attributable to the contribution of labour alone, but also to the contribution of other productive resources and to the effectiveness with which all are combined and organized for production.

On the other hand, the multifactor productivity accounts intend to measure the performance of the Canadian economy in production activities by taking the contributions of all productive resources into account. It is assumed that resources are optimally allocated between the various production activities so that the object of the performance indicators is solely to reveal the technical efficiency with which the available resources are used in each of these production activities or groups of activities.

In general, productivity gains are measured in a residual fashion as the growth in output not accounted for by the growth in production factors explicitly listed in the chosen formula. Multifactor productivity measures output per unit of all factors of production combined (such as labour, capital, materials and services used as inputs in the production of goods and services). Consequently, multifactor productivity does not reveal the contribution of the production factors but the joint effects of technical progress, economies of scale, and other factors not explicitly taken into account.

This publication presents two complementary categories of multifactor productivity indices. One category takes into account only the productivity gains made by an industry without considering the productivity gains made by its upstream suppliers. The other looks at the productivity gains made in the production of the goods and services of an industry by taking into account the productivity gains made by all industries which contributed directly and indirectly to that production. This measure basically consists in a measure of productivity by product category rather than by industry.

The first category of indices measures the growth in the gross output of an industry not accounted for by the growth in all of its factors of production; that is, both the inputs called primary, which are the labour and capital inputs, and the intermediate inputs, which are the materials and services purchased from other industries. This index does not take into account the productivity gains which take place in the industries which produce these intermediate inputs<sup>4</sup>. We will refer to this index as the **industry index**. Because the industry index does not account for the productivity gains realized in other industries, it can be viewed as a tool to assess productivity gains in a static partial equilibrium framework.

The second category of productivity indices takes into account the productivity gains realized in the upstream industries supplying intermediate inputs<sup>5</sup>. The index measures the growth in the output of an industry not accounted for by the growth in all its primary inputs as well as by the growth in the primary inputs used in the production of its intermediate inputs by its direct and indirect industry suppliers. In that

4. Except in variant of this index for intermediate inputs originating from the industry itself as will be explained below.

5. The concept and the empirical estimates were first introduced by T.K. Rymes and A. Cas in a study done for Statistics Canada between 1983 and 1985 and published later. See Cas A. and T.K. Rymes (1991), *On Concepts and Measures of Multifactor Productivity in Canada, 1961-1980*, Cambridge University Press, New York. However, contrary to Rymes and Cas, we include the capital stock in the primary inputs rather than in intermediate inputs.

perspective, the **interindustry** productivity index takes into account all the primary inputs which have been used in the business sector as a whole to produce a given bundle of goods and services. They may be seen as productivity indices attached to commodity bundles rather than to industries. These indices are called **interindustry** or **commodity (bundles)** indices.

Both measures of productivity are useful. For instance, in an effort to assess the performance of an economy as a whole in the production of some bundle of goods, it would be inappropriate to consider the declining industries with low productivity gains without also looking at the performance of the industries supplying them with goods and services. The latter industries, which may benefit from important productivity gains, may also be strongly dependent on the low performance industries for the sale of their output.

## 2.2 - The Concept and Measurement of Multifactor Productivity

The level of multifactor productivity is a ratio between the level of production of industries and the quantity of all inputs they use. Although there may be alternative ways to compute the productivity ratio, all of these consist in combining all the goods and services produced into a single aggregate output index and, likewise, all of the production factors used into a single aggregate input index. The aggregation of the goods and services produced or used in the production process requires that these goods and services be measured in some common units. Similarly to the weights and measures in physics, index numbers use the relative value of the goods and services at some specific point in time as the common unit of measure. They are in fact weighted averages where each good/service is attributed a weight according to its contribution to the value of the aggregate of which it is a part of. Thus, the greater the nominal value of the good/service, the larger share it will have in the aggregate<sup>6</sup>. The multifactor productivity index level is computed as the ratio of the aggregate output index to the aggregate input index. Productivity growth is positive if the aggregate output index grows faster than the aggregate input

index. Productivity decreases in the opposite case.

For empirical applications, some choices have to be made on how to actually measure inputs and outputs. The most widespread choice at the industry level is the **gross output** measure. The gross output of an industry is the aggregate volume of all goods and services produced and work done by the industry.

Gross output can be defined as either including or excluding intra-industry sales. When all intra-industry sales are removed, productivity growth is computed as if all establishments of the industry were integrated together into a single large establishment covering the whole industry. That establishment sells all its output outside the industry and buys all its inputs from without the industry. For that reason, these indices are called the **intra-industry integrated** productivity indices.

Correspondingly, on the input side, the measure of the index has to be inclusive of all used (and measurable) inputs which can be classified into two broad categories: (1) intermediate inputs which are comprised of the many goods (raw materials) and services purchased by the establishments of the industries, and (2) primary inputs including labour inputs, capital inputs, and natural resources. Intra-industry purchases are excluded in the intra-industry integrated indices.

More precisely, intermediate inputs are considered to be those inputs which are produced and are consumed during the same period (usually a year) by the business sector. The primary inputs are supplied from other sectors of the economy such as the household sector. Capital goods are commodities produced by the business sector like intermediate inputs. However, they are accumulated only if savings occur. Capital goods are supplied to the business sector at the beginning of each period by the households

---

6. This can be established more formally as the Divisia aggregation formula for a twice differentiable linearly homogeneous production function under competitive market conditions and profit maximization. The time continuous Divisia index is approximated by the chained Törnqvist index.

---

which are the asset holders of the economy. In addition, they are excluded from the intermediate input set on the ground that they are, by definition, not totally consumed during the period in which they have been produced. Households also supply labour inputs.

As discussed further below, imported inputs and a few other variables can also be included in the set of primary inputs or else be considered as intermediate inputs depending on which result one wants to obtain. Indeed, imported inputs are not produced by the business sector and, from that standpoint, could be considered as primary inputs. On the other hand, imports are produced inputs and therefore, although they are non domestic inputs, can be considered as intermediate inputs.

In the estimation of the multifactor productivity indices, a more detailed breakdown of both the inputs and outputs by commodity were used as described in Appendix 3. The more disaggregated (and consequently more homogeneous) set of commodities used improves the quality of the measured productivity indices and presents a definite advantage over the more aggregated (and more heterogeneous) set of commodities usually used by other investigators. However, due to statistical limitations, natural resources are not presently included in the input set. It is hoped that natural resources will be included in the future as estimates of their prices and uses become available. It is believed that this data shortage has implications mostly for the quality of estimates of resources industries but that it has little impact on the estimates of other industries.

The multifactor productivity indices have an important advantage over the partial labour productivity indices. This advantage stems from the inclusion of all the major factors contributing to the growth of output in the economy. Output growth is thus accounted for by increases in productive capacity, by a greater use of various services and goods purchased by industries (including energy) and by the growth in labour input. As mentioned above, output growth which is not accounted for by the growth of inputs is called productivity. Therefore, the more detailed and inclusive is the list of produc-

tion factors entering into the estimates, the more the growth in output can be "explained".

The inclusion of all production factors in the computation of productivity indices does not preclude the computation of meaningful indices of partial productivity. However, in order to analyse and to explain the partial productivity of any contributing production factor, one must first express its productivity in relation to the contribution of the other production factors. For instance, the index of partial labour productivity may have increased because the quantity of equipment, raw materials, and energy used per unit of labour have increased. Only when the contribution of these other factors have been netted out can the partial labour productivity be meaningfully related to factors such as education and experience.

Multifactor productivity presents a net advantage on this count compared to labour productivity, precisely because it allows the decomposition of increased labour productivity between the portion which comes from the contribution of the other production factors, and the portion which comes from factors explaining the increased efficiency of labour, such as education. The labour productivity indices presented in this publication do not allow such a decomposition.

The interindustry and the aggregate multifactor productivity indices take into account the productivity gains made in the production of the intermediate inputs while the industry indices based on gross output do not take these gains into account. Productivity indices based on gross output net of intra-industry sales take into account the productivity gains made by industries in the production of own used inputs but do not take into account productivity gains made in upstream industries.

Finally, all productivity indices consider capital goods as primary inputs, that is as non-produced inputs. Capital goods are nevertheless inputs that are produced by capital goods industries. Productivity gains made in the production of capital goods are not presently taken into account by any of the indices produced. The bias involved may be important. Indeed, if the econ-

omy was growing along a steady state growth path (along which the capital/output ratio would be fixed), its multifactor productivity gains would be equal to the partial labour productivity gains, were we to take into account the productivity gains made in the production of capital goods. We hope to be able to estimate these productivity gains in the future.

### 2.3 - Which Resources and How are they Measured?

Unemployed resources are excluded from the computation of productivity. Thus, for example, the labour input is measured with hours worked rather than with the available labour force. The productivity indices, consequently, do not measure the performance of the economy as a whole which is often reduced by the non-utilization of available resources. Rather, the productivity indices presented here intend to track the evolution of the technical performance of the production processes which would obviously not be well captured if unemployed resources were taken into account.

On the other hand, resources engaged in the production process may not be fully employed as is often the case in economic downturns. Labour hoarding is a classical example: in response to decreasing demand for its product, an establishment may not lay off its employees for various reasons such as separation costs and the cost of training new employees when operations expand later on.

An adjustment is made to take into account the capacity utilization rate of capital by calculating the cost of capital, that is, its share in the index of combined inputs, in a residual manner rather than by calculating it using the user-cost-of-capital approach (interest rates, depreciation rates, and other variables affecting the price of capital services)<sup>7</sup>.

However, this correction does not fully eliminate the cyclical fluctuations of the indices and,

consequently, does not reveal the trend followed by technical progress. This may be due to the fact that capital is not the only quasi-fixed factor. We just mentioned above the phenomena of labour hoarding. Short run disequilibrium may also act on the measure as well as scale economies and errors in the data.

However, over the long run, that is from peak to peak in economic activity, the indices do in fact reveal the increased productivity associated with technological possibilities, either in the form of technical progress or through a better use of all available technologies.

### 2.4 - Aggregate multifactor productivity

The discussion of the various concepts has hitherto been made with reference to the industry or commodity group as the main subject. What about multifactor productivity measures for the total business sector? What impact has the aggregation level on the definition of output and inputs? The answers to these questions are the main focus of this section.

If we wish to measure the productivity of the business sector as an integrated entity, only the production of goods and services sold outside the sector should be taken into account. Correspondingly, only the inputs coming from outside the sector should be accounted for. The industry productivity measure based on gross output then becomes inappropriate. The sum of the gross outputs of all industries in the business sector corresponds to much more than the out-bound production as it includes all goods and services bought by other industries and used as intermediate inputs in the production of other goods and services.

Let us consider the alternative intra-industry integrated output model, where intra-industry sales are netted out from both output and inputs. At the total business sector level all intermediate inputs, with the exception of imported inputs and inputs originating from other sectors of the economy, are intra-industry sales. The productivity index based on this model thus leaves, as output, the production of goods and services delivered to final demand and, as inputs, the resources available to the business

7. See Berndt, E.R. and Fuss, M.A., "Productivity Measurement with adjustments for variations in capacity utilization and other forms of temporary equilibrium", *Journal of Econometrics* 33 (1986) 7-29, North-Holland.

---

sector, that is its primary inputs of capital and labour and imported inputs and inputs supplied by other sectors of the economy.

This model considers the business sector as an entity whose establishments are integrated together but isolated from the rest of the economy and the rest of the world. The associated productivity measure does not take into account the productivity gains made in the production of imported inputs and inputs originating from other sectors. These inputs are considered as primary. It thus consists of a productivity measure which does not account for all productivity gains made in the economy.

By contrast, for the integrated world economy, goods and services exchanged between countries are intermediate inputs. In that perspective, productivity gains made in their production must be accounted for and these gains must be attributed to the respective producing economies. These inputs must be excluded from the primary input set of industries and their contribution to final sales (accounted for in their respective country's exports) netted out to retain only the capital and labour inputs and, as a counterpart, the value added of the business sector. The business sector is thereby seen as integrated to the world economy. We obtain in that fashion the most extensive measure of productivity of the business sector. This is the **value-added productivity index**.

## 2.5 - Usefulness of Productivity Indices in Economic Analysis

As indicated above, the main purpose of the multifactor productivity measures is to separate the observed growth in industrial production into increases in the economic resources employed by industries and increases in overall efficiency. This step allows a more complete accounting of the sources of economic growth than the partial measures presented in the framework of the Canadian System of National Accounts. Time series of multifactor productivity by industry also allow analysts to measure trends and detect shifts in competitive advantages among various Canadian industries vis-à-vis similar industries in the rest of the global economy. By showing how industries' evolution

has been influenced by their technical performance, the assessment of multifactor productivity helps analysts and policy makers to address such issues as domestic industrial policy and international industrial strategy. Similarly, businesses and other private organizations observe productivity movements to evaluate the long-term viability of various industries and make more informed investment decisions.

In addition, proper growth accounting opens the way to a better understanding of the sources of productivity growth. The latter can be conceptually decomposed into three components: economies of scales, technical progress and measurement errors due to omitted factors. Growth accounting paves the way to further analysis of the sources of economies of scale and technical progress. Taking technical progress as an example, it could be defined as the general advance in knowledge. If we accept this definition, then, over the long run, technical progress is the only source of permanent and sustained improvement in productivity. Indeed, at any point in time, the level of education of workers may be raised only to a certain limit through investments in education. Similarly, the diffusion of the best known technologies through investments in physical equipment has a limit as well as the best use of existing technical possibilities through economies of scale. Only investments in fundamental research in both human and natural sciences and investments in applied research and development can lead to a better and more educated labour force and better equipment over the very long run. Measuring the contribution of technical progress to the growth in output helps in understanding the importance of society's investment in such research.

## APPENDIX 2

### Sources of Data

This Appendix includes a description of data sources employed in the production of labour and multifactor productivity indices. As indicated in Appendix 1, labour productivity indices are not produced as partial multifactor productivity indices. Because both these index types are derived in part from different data sources, we describe their sources separately. More specifically, labour productivity indices are based on Laspeyres indices of Gross Domestic Product while multifactor productivity indices are calculated mainly from Törnqvist indices of gross and net-gross output. In spite of these differences, the measure of labour hours are identical in both productivity measures.

The description of data sources is divided in two categories depending on whether data are preliminary or final. Final data are based on benchmarked data from the Input-Output Accounts as well as on statistics obtained from censuses and surveys, while preliminary data are based on other more up to date but less reliable data.

#### 1 - Description of Labour Productivity Data

##### 1.1 - Output

The output data used to calculate the indices of labour productivity and unit labour cost are the estimates of constant price Gross Domestic Product at factor cost by industry. The following sources are utilized: *The Input-Output Structure of the Canadian Economy in Constant Prices* (Catalogue 15-202) and *Gross Domestic Product by Industry* (Catalogue 15-001) for the years following the benchmark year. The data on real GDP in the Finance, Insurance and Real Estate Industries excludes real GDP of government royalties on natural resources and rents of owner occupied dwellings.

##### 1.2 - Labour Input

The indices of productivity employ the number of hours worked. Hours worked are computed

from the number of persons at work and the average annual hours worked. The description of sources for the employment and hours estimates applicable to the last four years are presented below<sup>1</sup>.

##### 1.2.1 - Estimations of Persons at work

**Persons at work.** Persons at work are made up of two groups: paid workers and other-than-paid workers. The other-than-paid workers include self-employed and unpaid family workers. Up to the year of the preliminary input-output tables, the paid workers and other-than-paid workers estimates are produced at the most detailed level of the System of National Accounts. This represents employment estimates for 216 different industries, including the non-commercial sector.

Beginning in 1988, an important change has been made to the estimates of persons at work used in measures of productivity. The number of persons at work obtained as the average of the aggregation of the estimates of all industries obtained from different sources is reconciled to the employment obtained by applying the growth rate of total employment obtained from the Labour Force Survey to the 1987 employment level. The growth rate of commercial and non-commercial employment obtained from this survey also serves as annual benchmark. Any difference between the estimates is allocated between the trade industries and the Community, Business and Personal Services (excluding education and hospital industries) because employment data for these industries are con-

1. For further details about labour input data sources, the reader is referred to *Indexes of Output Per Person Employed and Per Man-hour in Canada, Commercial Non-agricultural Industries, 1947-1963* (Catalogue 14-501) for the years 1946 to 1961 and to: Karnail S. Gill and Monique Larose, *Sources and Methods of Estimating Employment by Input-Output Industries 1961-1989*, Input-Output Division, Technical Series, #47, 1991.

---

sidered less reliable. The same method is applied to the preliminary data described below.

### Benchmark data

**Paid workers.** The number of paid workers including multiple job holders in agriculture, fishing and trapping industries as well as for wholesale trade, and the accommodation and food industries is taken from the *Labour Force Survey* (Catalogue 71-001).

The mining, quarrying and oil well industries are broken down into four major groups according to the 1980 SIC:

1. Mining industries;
2. Crude petroleum and natural gas industries;
3. Quarry and sand pit industries;
4. Service related to mineral extraction.

The primary data source used for the first three groups is the *General Review of the Mineral Industries*, (Catalogue 26-201). The only exception is the oil sands industry, which falls into the second major group, crude petroleum and natural gas industries. This industry is not covered in the *General Review of the Mineral Industries*, and therefore the data used for this industry are taken from the Survey of Employment Payroll and Hours. The last major group, service industries incidental to mineral extraction, *Employment, Earnings and Hours*, Catalogue 72-002 has been used.

The source of the number of paid workers in manufacturing is *Manufacturing Industries of Canada: National and Provincial Areas* (Catalogue 31-203) a publication from the annual survey of manufactures.

The publication *Employment, Payroll and Hours* (Catalogue 72-002) is the source for the following industries:

- Logging and forestry industries;
- Construction industries (contract work);
- Transportation and storage industries;
- Other utility industries;
- Finance, insurance and real estate industries;
- Business service Industries;

- Educational service industries;
- Health and social services industries;
- Personal and other service industries;
- Non-commercial services.

In transportation and storage industries the following publications were used to derive the number of paid workers: *Air Carrier Operations in Canada* (Catalogue 51-002), *Rail Transport* (Catalogue 52-212; 52-215 and 52-216), *Gas Utilities: transportation and distribution systems* (Catalogue 57-205) and *Oil Pipeline Transport* (Catalogue 55-201), *Passenger Bus and Urban Transit Statistics* (Catalogue 53-215).

In the case of the four communication industries, paid workers data were obtained from: *Radio and Television Broadcasting* (Catalogue 56-204); *Cable Television* (Catalogue 56-205), and *Canada Post Corporation Annual*.

Among the industries in the above list, the construction industry requires a clarification. The Input-Output concept of the construction industry includes the construction activity contracted out as well as the activity carried out by the work force of all other industries. The latter activity is named Own-Account Construction. Given a lack of data on the employment directly affected to own-account construction, such employment is estimated from data on labour remuneration cost obtained from *Construction in Canada*, (Catalogue 64-201). The volume of labour employed in this activity is obtained as the ratio between own-account construction labour compensation and the average wage in the industry where the activity takes place. These volume is subsequently transferred to the business sector construction industry. In the 1980s, own-account construction activity represented about 25% of total construction activity.

**Other-Than-Paid workers.** The main data source for other-than-paid workers is the Labour Force Survey. However, the number of self-employed workers, medical doctors and dentists that belong to the Health and Social Services Industries (except hospitals) are obtained from *Fiscal Statistics*, Revenue Canada Taxation, (Catalogue RV 44).

---

## Preliminary data for the recent years

Preliminary data for the two most recent years are produced only at the "S" level of aggregation of the Input-Output tables. For the paid workers, the year-to-year change from Labour Force Survey (LFS) and Survey of Employment Payroll and Hours (SEPH) was applied to the absolute values of the last benchmark year. For other-than-paid workers, the data were obtained entirely from the Labour Force Survey.

### 1.2.2 - Estimation of hours worked

**Hours worked.** The number of hours worked for each industry is obtained by the product between the number of persons at work and the average number of hours worked per person per year. Given the availability of employment data, the estimation of hour worked consist of estimating the average hours worked per year.

#### Benchmark data<sup>2</sup>

The estimation of average hours worked per year up to the benchmark year is made at the "PL" aggregation level, i.e., for 122 industries. With the exception of the mining and manufacturing industries, all data on average hours worked are from the Labour Force Survey.

Monthly data from the Labour Force Survey refer only to the survey week, usually the week falling on the 15th day of the month. Respondents having worked during the reference week are asked a series of questions on hours worked. The questions concern regular hours, overtime hours, hours effectively worked as well as hours lost and the reason for work absence. This information allows a verification of each element of the response on hours and permits the estimation of total annual hours worked. Given that the statistics refer to a precise week of the month, annual data represent only the observation of hours corresponding to 12 survey weeks

during the year. To estimate the effective hours worked during the all weeks of the year, a methodology was developed in the Productivity Measurement Section<sup>3</sup>. The goal of the methodology is to adjust the hours effectively worked reported by the survey in relation to two factors. One is the effect of holidays falling in the reference week, the other being the effect of time lost due to labour conflicts<sup>4</sup>.

The method used to estimate annual hours worked from data originating in the Labour Force Survey has four main stages:

- 1 - The first consists of adding estimates of hours lost due to holidays or labour conflict to the estimates of hours worked during the reference week. The result is an estimate of the hours than would have been worked in the absence of conflicts and holidays. These monthly data are then interpolated in order to obtain the estimates for the 52 weeks of the year.
- 2 - The second stage is to adjust the estimates of hours worked by the hours lost due to holidays. This information is obtained directly from the Labour Force Survey in the case of holidays during the survey week. Those not in the survey week are estimated. This is done by identifying and classifying the main Canadian holidays in three categories 1) Most important (Christmas, New Year, Easter Monday, Canada Day, Labour Day, Thanksgiving), b) Important (Victoria Day, Boxing Day), and 3) less important (Easter Monday, St. Jean Baptiste/Civic Holiday, Remembrance Day)<sup>5</sup>. The classification reflects the fact that most employees have the right to

---

2. For further details on hours worked data sources used to measure productivity indices for the years 1961 to 1988, see the feature article entitled "Hours Worked: A New Measure of Labour Input for Multi-factor Productivity" by Jean-Pierre Maynard, *Aggregate Productivity Measures 1991*, Catalogue no. 15-204E.

3. For a complete description of this methodology, see Maryanne Webber, *Estimating Total Annual Hours Worked from the Canadian Labour Force Survey*, Input-Output Division, Technical Series, #51, Statistics Canada, April 1983.

4. The employment concept of the Labour Force Survey includes as employees, any respondents that did not work during survey week due to labour disputes.

5. The classification of statutory holidays in order of importance comes from data collected by the Pay Research Bureau, a service of the Public Service Staff Relations Board of the Federal Public Service.

the important holidays and that a smaller proportion have the right to other holidays. The number of hours lost for the three holiday types is estimated based on those of holidays corresponding to the same category falling during the survey week.

3 -The third stage consists of removing hours lost due to labour conflict<sup>6</sup>. It must be noted that only the statistics on paid workers are adjusted for this type of absence.

4 -Finally, the average annual weekly hours worked is obtained by the average weekly hours after adjustment for labour stoppage and holidays. The average number of hours worked per year is obtained as the product of the weekly average by the number of weeks in the year. This last component is not constant but follows the vagaries of the calendar. A calendar year comprises 52 full weeks plus one day (two in leap years); if any of these days fall on a non-working day, the year has exactly 52 weeks, and exceeding this in all other cases. As a result, the number of hours worked may change from year to year due to fluctuations in the length of the year.

This method permits the estimation of average hours worked for paid workers with the exception of the mining and manufacturing industries and for the other-than-paid category for all industries, except manufacturing industries.

Data for the manufacturing industries are obtained from the annual Survey of Manufactures as well as from other surveys. The calculation of hour worked by production workers is different from that of salaried workers. The number of hours worked by production workers is obtained directly from the annual Survey of Manufactures. In the case of salaried workers, the survey only collects information on normal work hours and number of vacation days. The average hours worked by this last group are obtained by deducting from normal hours the

number of hours not worked due to vacations and holidays. In the case of self-employed workers it is assumed that they work the same average hours as the paid workers in the same industry.

Hours worked data for each of the four mining industries are subject to a special methodology. The estimates for metal mines, non-metal mines and sand and quarrying and sand pits are estimated on the basis of data on hours worked by production workers derived from the Census of Mines to which we add the average hours paid of salaried employees from the Survey on Employment, Payroll and Hours. The latter are adjusted by means of data on average hours of paid absence calculated as the difference between hours paid and hours worked by production workers. Average hours for the oil and gas industry are obtained directly from the Labour Force Survey. Average hours in mining services are obtained from data on hours paid in the Survey of employment, Payroll and Hours to which an adjustment is made for time lost. To reflect the total paid workers for this industry, the total hours worked of the Labour Force Survey at aggregation level "S" (excluding oil and gas) is used as benchmark and allocated proportional to the share of each component estimated from the different sources described above.

### Preliminary data

In the case of recent years for which no Survey of Manufactures or Census of Mines data are available, we project benchmark data by the growth rate of hours worked of the Labour Force Survey.

### 1.3 - Labour Compensation

There are two components to **labour compensation**: labour income of paid workers and an imputed labour income of self-employed workers. The labour income of paid workers is taken from *The Input-Output Structure of the Canadian Economy* (Catalogue 15-201), up to and including the year of preliminary tables. Data for the two most recent years are taken from *Estimates of Labour Income* (Catalogue 72-005) after adjustments are made to reroute own-account con-

6. For more information concerning this survey, refer to *Collective Bargaining Review*, Labour Canada, monthly.

struction to construction industries of the business sector.

**Labour income of other-than-paid workers.** In addition to the labour income of paid workers, labour compensation includes an imputed labour income for all other-than-paid workers except unpaid family workers. The imputation is based on the assumption that the hourly income for the labour of self-employed persons is the same as that of paid worker in the same year and the same industry.

An adjustment is made in the case of some professional persons, such as doctors, dentists, lawyers, accountants and engineers. These occupations are largely self-employed, but the average earnings of paid workers in the same industry division underestimates the earnings of these occupations. In these cases their average labour income are obtained from *Taxation Statistics*, Revenue Canada Taxation, (Catalogue RV 44).

## 2 - Description of Multifactor Productivity Data

### 2.1 - Introduction

Prices and volumes for inputs and outputs used in multifactor productivity indices are based on estimates from several sources. For outputs and intermediate inputs by industry, the data are obtained from the current and constant price Canadian input-output tables<sup>7</sup>. Some transformation of these data are required to obtain better conceptual measures for the purpose of estimating multifactor productivity. These transformations are summarized in this appendix. Primary input cost are also taken from input-output tables while their volumes are estimated from other sources. Labour input data are taken from the labour productivity program. Capital input data are described in a technical note which is summarized below<sup>8</sup>. The industry coverage of the business sector used for multifactor productivity estimates differ slightly from

the usual definition of the national accounts as explained in more detailed in Appendix 3.

### 2.2 - Input-Output Commodity Data

The input-output tables are estimated at both producers' and purchasers' prices. Producers' prices are the prices received by the sellers at the boundary of their establishments. Purchasers' prices correspond to the market prices at the point of delivery and include various margins which are not taken into account in the producers' prices. Some of these margins are paid to business sector enterprises in exchange for real services such as retail and wholesale services and transportation services. Commodity indirect tax margins, on the other hand, represent a pure transfer without any real counterpart.

As the proposed productivity measures are derived under the assumption of competitive market behaviour, it can be argued that outputs of industries should be valued at producers' prices while the inputs should be valued at purchasers' prices. The Törnqvist index of productivity growth, which is used here, rests on the assumption of profit maximizing behaviour of firms in competitive markets. This implies that the marginal product of each input be equated to its real price defined as the purchasing cost on the input including all margins divided by the net selling price of the output, excluding all margins. But as real margins represent real inputs which can be substituted for other inputs over the long run, they were considered as distinct inputs rather than included in the physical volumes of the other inputs. Tax margins were included in the input set.

Conceptually, operating subsidies can be considered as negative indirect taxes. therefore, They were distributed over the input and output commodities to which they apply. Some subsidies, however, could not be attributed to specific commodities and were treated as non-commodity indirect taxes (see below).

7. For informations on data sources and concepts, refer to the *Input-Output Structures of the Canadian Economy, 1961-1981*, (Revised Data), Statistics Canada, Catalogue no. 15-510, Input-Output Division, 1987, pp. 1-127.

8. For a detailed documentation on capital input, see M. Salem et al. *Documentation of Capital Input and Capital Cost Time Series for Multifactor Productivity Measures*, Statistics Canada, Input-Output Division, September 1993.

Royalties were considered taxes levied on industries' outputs in the productivity accounts. They were subtracted from the producers' prices of outputs to estimate the net price received by producers. Royalties are considered as a rental income on natural resources received by the business sector industry Government Royalties on Natural Resources in the input-output tables. However, this is an improperly defined industry for productivity analysis as it has no inputs except for the Other Operating Surplus which is equated to the royalties received. The industry was also excluded on the grounds that it appeared doubtful that government act as a real monopoly on natural resources industries. Royalties will be introduced as part of the rental income of natural resources when estimates of the quantities of these resources become available.

Input and output volumes for goods and services were taken from producer price input-output tables without any adjustment. The reason is that in constant prices, commodity indirect taxes represent a fixed proportion of inputs calculated for the base year such that their inclusion does not affect the growth rate of volumes.

Dummy industries have been removed from the input-output tables. Corresponding dummy commodity inputs have been transformed into real inputs on the basis of the input structure of dummy industries.

### 2.3 - Labour Input at Current and Constant Prices

The employment and hours estimates agree with those used in the estimates of labour productivity. Sources were described in the first part of this appendix.

Labour compensation data are also identical to those used in labour productivity. However, it is important to mention that the imputation of self-employed income is deducted from the net revenue of individual businesses in the industry in order to maintain the accounting balance of the system. In addition, multifactor productivity labour input is weighted by the share of wages while labour productivity labour input is not weighted. Labour productivity labour input will

be weighted once the labour productivity estimates will be obtained from the multifactor productivity estimates. This will recognize the heterogeneity of labour categories.

### 2.4 - Capital Input at Current and Constant Prices

The input of capital services for a given year is assumed to be proportional to the capital stock in constant prices at the end of the previous year, net of depreciation. Capital stock excludes investments made during the current year because, in general, they are not productive at this stage. Depreciation follows a geometric curve<sup>9</sup>.

One particular problem occurs when using the net capital stock figures from the Investment and Capital Stock Division: these data are estimated for industries including all establishments, not only business sector ones as is the case of the input-output tables. Non-business industry capital stock was estimated and removed from the industries where significant differences were known to exist, namely, in non-metal mines, chemicals and chemical products, and other utility industries.

Contrary to the estimates of intermediate and labour inputs, capital input cost is estimated residually. It corresponds to the sum of other operating surplus (that is a residual item in the input-output tables), the net revenue of unincorporated businesses less the labour income of self-employed workers. Indirect taxes other than those on goods and services are added to the cost of capital (subsidies are deducted), because these taxes apply generally to property and the use of capital by the industry. The capital service price is calculated as the ratio between capital cost and the stock of capital of the previous year in constant prices.

9. In Canada - U.S. comparisons, one must note that, in the Canadian measure of the capital stock, a more accelerated depreciation pattern is being used. For a more technical description of the new capital asset series, see *Fixed Capital Flows and Stocks, Methodology*, Investment and Capital Stock Division, Statistics Canada, May 1990.

## APPENDIX 3

### Aggregation Parameters for Productivity Measures

---

The statistics presented in this publication refer to business sector industries, as defined in the Canadian System of National Accounts. There are no corresponding statistics for non-business sector industries due to difficulties in the measurement of real output in this sector, as explained in Appendix 1.

The most detailed account of the business sector is defined in terms of individual industries from the *Standard Industrial Classification* (SIC). Aggregation of SIC industries generates 154 link (L) level industries (excluding the fictive industries), 47 medium (M) level industries and 13 small (S) level industries. The industrial coverage of the business sector departs slightly from the current definition of the Canadian System of National Accounts as some components were excluded. Government Royalties on Natural Resources (industry L 140), and Owner Occupied Dwellings (industry L 141) were considered to be improperly defined industries for productivity analysis.

Granted the previously mentioned exceptions, labour productivity is evaluated at the link level industries but reported at the medium and small level industries. More detailed statistics are available on request, but subject to confidentiality criterias. For the purpose of deriving multifactor productivity growth rates, the inputs in goods and services were taken from the input-output tables at their most disaggregated level<sup>1</sup> (about 600 commodities). However, it was not possible to use the inputs or outputs by industry at their link level because capital stock series were not available at that level of detail. Input-output tables have been aggregated to a special level of aggregation -- identified as PL -- for the multifactor productivity measures which consists of 122 business sector industries. Moreover,

two more link level industries had to be dropped for lack of data on capital stock needed for the calculation of multifactor productivity growth. These industries are Laundries and cleaners (industry L 151) and Other personal services (industry L 152).

There are a total of 33 statistical tables on labour productivity appearing in Part 2 of this publication. Tables 1 to 4 are produced for special aggregates of business sector industries. Tables 5 to 12 correspond to selected S level business sector industries. The remaining tables, 13 to 33, are associated with the M level of the manufacturing industries.

Table 1 below shows the concordance between link level, medium level and small level industries of the Canadian System of National Accounts with the *Standard Industrial Classification* of 1980 and with the special aggregation (PL) used for the multifactor productivity estimates. Table 2 indicates PL level industries for which we have incomplete data. For these industries, we have assumed that the rate of growth of the available data reflects also the growth of the uncovered subset; the bias introduced this way is probably minor. Table 3 presents special aggregations used in section 2 of this publication.

---

1. It was impossible, at this stage, to include a measure of natural resources such as land used as inputs. Natural resources are believed to be important mostly for primary industries but to play only a minor role in other industries.

**Table 1 - Concordance between link codes (L), standard industrial classification codes (SIC) special PL codes, medium level (M) and small level (S) industry codes**

| L Level Industries |  |                                 |         |        |        |
|--------------------|--|---------------------------------|---------|--------|--------|
| Link Code          | Industry Title                             | 1980 SIC                        | Code PL | Code M | Code S |
| 1                  | Agricultural & related services industries | 011-023                         | 1       | 1      | 1      |
| 2                  | Fishing & trapping industries              | 031-033                         | 2       | 2      | 2      |

\* Productivity measures are calculated at the most detailed level possible given the available data and reasonable hypotheses. In so doing, we obtain labour productivity measures for 152 industries of the link aggregation. Lack of data on capital stock restricts us to multifactor productivity estimates of 122 industries of the special PL aggregation. Moreover, no capital stock data is available for laundries and cleaners and other personal services.

**Table 2 - Concordance between 1980 SIC industries for which there is no capital stock data and special aggregation PL industries**

| Industry Title  | Code S    |
|---|-----------|
| Business sector industries                                  | 1-13      |
| Business sector - goods                                     | 1-6,9     |
| Business sector - services                                  | 7-8,10-13 |
| Business sector - excluding agricultural & related services | 2-13      |

## APPENDIX 4

### Quality Rating of Productivity Estimates and Related Data

This appendix provides quality ratings of labour productivity and related data and of multifactor productivity data, including the ratings of the input and output components used to estimate these measures. Quality ratings are provided for the last benchmark year as noted on the following tables. Data quality ratings for previous years may be found in preceding issues of this publication; data for the period following the benchmark year are deemed to be of lesser quality although no quality rating is provided.

#### 1 - Quality Rating of Labour Productivity Estimates and Related Data

Like other components of the Canadian System of National Accounts (CSNA), the labour productivity and related data presented in this publication are derived from a variety of sources and subjected to various adjustments. Assessing the quality of the data thus raises difficulties similar to those pointed out in other CSNA publications. The labour productivity and related data presented in this publication are derived from:

- (1) input-output tables, and real gross domestic product by industry, and,
- (2) various surveys and censuses containing information on employment, hours worked, and labour income.

In rating various data our main interest lies more in year-to-year changes than in the levels of various constructs. No attempt will be made to establish a cardinal rating of these constructs used in productivity. However, based on an informed opinion, an ordinal rating will be attempted. The rank of 1 means most reliable, the rank of 2 means reliable and the rank of 3 means acceptable. All the series mentioned below received a rank. They are shown in tables 1 and 2.

- (i) Real GDP at factor cost;
- (ii) Persons at work;
- (iii) Average hours;
- (iv) Hours worked;
- (v) Labour compensation;
- (vi) Real GDP per hour worked;
- (vii) Compensation per person at work;
- (viii) Hourly compensation;
- (ix) Unit labour cost.

**Real GDP.** The quality ratings of real GDP have been taken from Appendix A of the publication: *The Input-Output Structure of the Canadian Economy, 1991* (Catalogue 15-201).

**Persons at work.** For these data, the rankings have been determined as follows: in general a rank of 1 has been assigned to the most reliable estimates that are based completely on censuses, survey or administrative records<sup>1</sup> with minimum adjustments for coverage, valuation and classification. A rank of 2 has been assigned to less reliable census and survey data with adjustments for coverage. A rank of 3 has been assigned to all other sources for which it has been necessary to make adjustments for classification based on professional judgement, or that are estimated from proxy indicators. It is important to note that the rating of survey series is also based on their estimated coefficient of variation. In general, the coefficient of variation is inversely proportional to the size of the industry.

Relationship between the coefficient of variation and the ordinal ratings:

| Ratings | Range of coefficient of variation |
|---------|-----------------------------------|
| 1       | 0.0% to 2.5%                      |
| 2       | 2.6% to 5.0%                      |
| 3       | 5.0% and over                     |

1. See Appendix 2 for a full description of data sources.

**Table 1 - Quality ratings of labour productivity and related data at aggregation level S and business sector, 1992**

| Industry title                                    | Real GDP | Persons at work | Average hours | Hours worked | Labour compensation | Real GDP per hour worked | Compensation per person | Hourly compensation | Unit labour cost |
|---|----------|-----------------|---------------|--------------|---------------------|--------------------------|-------------------------|---------------------|------------------|
| Agricultural & related services industries        | 2        | 3               | 2             | 3            | 3                   | 3                        | 3                       | 3                   | 3                |
| Manufacturing industries                          | 1        | 1               | 1             | 1            | 1                   | 1                        | 1                       | 1                   | 1                |
| Construction industries                           | 3        | 2               | 2             | 2            | 2                   | 2                        | 2                       | 2                   | 3                |
| Transportation & storage industries               | 2        | 2               | 1             | 2            | 2                   | 2                        | 2                       | 2                   | 2                |
| Communication industries                          | 2        | 1               | 1             | 1            | 1                   | 2                        | 1                       | 1                   | 2                |
| Wholesale trade industries                        | 3        | 1               | 1             | 1            | 1                   | 2                        | 1                       | 1                   | 2                |
| Retail trade industries                           | 3        | 2               | 1             | 2            | 2                   | 2                        | 2                       | 2                   | 3                |
| Community, business, personal services industries | 2        | 2               | 1             | 2            | 2                   | 2                        | 2                       | 2                   | 2                |
| Business sector industries                        | 1        | 1               | 1             | 1            | 2                   | 1                        | 1                       | 1                   | 1                |

**Table 2 - Quality ratings of labour productivity and related data for manufacturing industries at aggregation level M, 1992**

| Industry title                                | Real GDP | Persons at work | Average hours | Hours worked | Labour compensation | Real GDP per hour worked | Compensation per person | Hourly compensation | Unit labour cost |
|---|----------|-----------------|---------------|--------------|---------------------|--------------------------|-------------------------|---------------------|------------------|

| Fabricated metal products ind.                | 1        | 3               | 2             | 3            | 1                   | 2                        | 2                       | 2                   | 1                |
| Machinery industries                          | 1        | 2               | 1             | 2            | 1                   | 1                        | 2                       | 1                   | 1                |
| Transportation equipment ind.                 | 2        | 1               | 1             | 1            | 1                   | 2                        | 1                       | 1                   | 2                |
| Electrical & electronic products industries   | 2        | 2               | 2             | 2            | 1                   | 2                        | 2                       | 2                   | 2                |
| Non-metallic mineral products industries      | 1        | 2               | 1             | 2            | 1                   | 1                        | 2                       | 1                   | 1                |
| Refined petroleum & coal products industries  | 2        | 1               | 2             | 2            | 1                   | 2                        | 1                       | 1                   | 2                |
| Chemical & chemical products industries       | 2        | 1               | 2             | 2            | 1                   | 2                        | 1                       | 1                   | 2                |
| Other manufacturing industries                | 2        | 3               | 2             | 3            | 1                   | 2                        | 2                       | 2                   | 2                |

According to these criteria, the 1991 employment data from the Annual Survey of Manufactures at the S level of aggregation, for example, carry a ranking of 1. The main deficiency of the data comes from the fact that employment for a significant segment of employment in small businesses is estimated from Revenue Canada payroll files. Thus, a ranking of 1 has been assigned where less than 10.0% of the employment data is estimated from payroll data. A ranking of 2 has been assigned to data where more than 10.0% but less than 20.0% of the data is from this source. A ranking of 3 has been assigned above 20.0%.

In addition to being ranked according to the coefficient of variation, the data that come from the Labour Force Survey were also evaluated according to the proportion of multiple jobholders. These workers are only classified according to their primary job. It should be noted that the number of persons at work includes paid workers, self employed and unpaid family workers. Since for each industry there is at least one of the three categories estimated from the Labour Force Survey, all employment estimates are more or less affected by the classification problems of multiple job holders. A ranking of 1 has been assigned to the industry where multiple job holders represented less than 4.0% of total employment. For industries where this ratio is between 4.0% and less than 6.0%, the ranking is 2, while those where this percentage is 6.0% or greater obtained a ranking of 3. Consequently, the quality ordinal rating of employment data comes from at least two criteria<sup>2</sup> for all industries. The employment ratings shown in the tables of this appendix correspond to the rounded average of the assigned ratings according to the criteria described above.

**Hours worked.** The number of hours worked in each industry is obtained as the product of the number of persons at work and the average number of hours worked in each year. Except for manufacturing, all hours data are taken from

the Labour Force Survey. As in the case of employment, the quality of average hours worked from this survey depends mainly on the estimated coefficient of variation of these series. All industries published at the S level obtained a ranking of 1, except for agriculture. For manufacturing industries at the M level, average hours worked come either from the Labour Force Survey or from the Annual Survey of Manufactures. When the source used is the Annual Survey of Manufactures, average hours worked were assigned a quality rating equal or lower than the one received by the number of persons at work. Since hours worked are obtained as the product of average hours worked and the number of persons at work, their quality rating corresponds to the rounded average of the two variables.

**Labour compensation.** Labour compensation is the sum of labour income of paid workers and the imputed labour income of self-employed workers. Since the estimates of labour income in the benchmark year come from administrative data and have been subjected to various Input-Output adjustments, these have a rating of one. However, in some industries (for example Agriculture, Construction, Retail Trade) there is a large number of self-employed workers for whom there is no direct measure of labour income and an imputation is made on the assumption that the hourly compensation of self-employed workers equals that of paid workers. Therefore, at aggregation level S the following rating criteria has been used. For industries, where the ratio of self-employed workers to persons at work is less than 10.0% the rating of labour compensation data is 1, where this ratio is 10.0% and 20.0% the rating is 2. For a ratio greater than 20.0% a rating of 3 has been assigned. According to these criteria, compensation data for all manufacturing industries at M level of aggregation have been assigned a quality rating of 1.

**Labour productivity and related data.** The quality ratings of ratios like real GDP per person at work, real GDP per hour worked and unit labour cost have been calculated as the rounded weighted average of the ratings for the two variables. For example, if the rating for real GDP is

2. Some industries at level S are obtained through the aggregation of their subgroups at a detailed level which are composed of more than one source. Thus, the rating at S level correspond to the average weighted rating of each component.

1, and employment is 2, then the rating for real GDP per person at work is 2.

## 2 - Quality Rating of Multifactor Productivity Estimates and Related Data

The quality rating for multifactor productivity at all levels of aggregation relies on the quality rating for gross output, intermediate inputs, capital, and labour, except for that of the business sector which depends on the quality rating for value-added, for capital, and for labour.

Intermediate inputs and gross output in current and constant prices and gross domestic product (GDP) carry the quality ratings described in Appendix A of *The Input-Output Structure of the Canadian Economy*, catalogue number 15-201. Capital input data quality is based on the ratings of business investment as given in the above

mentioned publication. The quality ratings of employment, hours worked and labour compensation are discussed in section 1 of this appendix.

The quality ratings of basic data at the S and M aggregation levels (refer to Appendix 3 for more information on aggregation levels) are obtained by weighting the disaggregated quality ratings using value shares as weights. The quality assessment of multifactor productivity estimates is then based on the combined quality ratings of outputs, labour inputs, capital inputs, and, if applicable, intermediate inputs, according to their respective value shares. Quality ratings of basic data shown in tables 3 and 4 of this appendix are rounded to the nearest highest rating to account for the quality-increasing effect of aggregation.

**Table 3 - Quality ratings for the components of multifactor productivity estimates by industry at aggregation level S and for the total business sector, 1992**

| Industry Title                       | Gross Output |     | Labour Inputs |        |        | Capital Inputs |     | Intermediate Inputs |     | GDP |     | MFP Index |

| Labour compensation per person at work                 | 7931 |
| Labour compensation per hour worked of persons at work | 7932 |
| Unit labour cost                                       | 7933 |

# Let us Make Productivity Work for You

---

Through various means of disseminating the data contained in this publication, Statistics Canada is able to accommodate the specific, yet differing needs of users. Productivity and related data are available in a variety of formats and released at different times during the year.

## The Daily

If you want the information at the earliest possible date, and you only required summarized data, then the Daily is probably what you need. The productivity data are released twice a year, generally around March 31st and October 31st. The Daily is available on the Internet on the World Wide Web (<http://www.statcan.ca>) or on the Statistics Canada's gopher service, Talon (gopher.gopher.statcan.ca). To have the Daily delivered directly to your computer, just request a subscription by sending an e-mail to [listproc@statcan.ca](mailto:listproc@statcan.ca). Best of all, e-mail subscriptions are free.

## CANSIM

CANSIM (Canadian Socio-Economic Information Management System) is the Registered Trade Mark for Statistics Canada's machine-readable database. You can have immediate access to Statistics Canada's most current productivity data, in its fullest detail via CANSIM. You can obtain access to the CANSIM database directly, through your computer terminal (or, we can extract the required information for you on print-outs, or in machine-readable form). Productivity data is released to CANSIM twice a year, concurrently with the relevant releases of *The Daily*. Call (613) 951-8200 to place CANSIM requests.

## Annual Publication

In the annual publication *Aggregate Productivity Measures* (catalogue 15-204E), productivity and related measures by industry are presented, illustrated, and analyzed. Documentation is also included in this publication describing the concepts, sources, and methods underlying the construction of these measures. Call toll free 1-800-267-6677 to order the publication at a price of \$44.

## Special Requests

For those of you who have more specific data needs we also process customized requests, the results of which can be produced either on print-outs or on diskettes. Requests can be processed as soon as the data are released and therefore the results can be obtained months in advance of the annual publication. Call R. Rioux, Consulting and Marketing, at (613) 951-3697 to place your special request.

---

## Technical Series

A series of technical papers for users interested in productivity accounting and Input-Output tables and modeling and related research is available on request; please contact R.Rioux, Consulting and Marketing, (613) 951-3697.

For further information mail this coupon to: Consulting and Marketing, Input-Output Division, Statistics Canada, 23rd floor, R.H. Coats Building, Ottawa, Ontario, Canada, K1A 0T6.

# Canada

✓ **Identify  
Emerging Trends**

✓ **Define New  
Markets**

✓ **Pinpoint Profit  
Opportunities**

**T**o safeguard your place in tomorrow's marketplace, you have to be able to anticipate trends today. To do that, you're going to need some insight into the purchasing trends in the Canadian marketplace.

With a complete profile of Canadian consumers, plus an indepth analysis of Canadian industries, the **Market**

**Research Handbook** gives you the most thorough coverage of purchasing trends. This valued bestseller can lead you to new markets by giving you details on:

- ▶ how much money Canadians are earning and what they're spending on cars, rent, home entertainment and household appliances;
- ▶ the level of sales in retail chain and department stores;
- ▶ what goods are being traded between Canada, U.S., and other countries;
- ▶ census data such as: age/sex, schooling, households, unemployment, interprovincial and international migration

...and much, much more!

With over 600 pages, the **Handbook** includes more than 200 statistical tables that give you instant access to provincial and national

market data. Featured are important economic indicators such as the **Gross Domestic Product, Labour Force Productivity, Private and Public Investment** and the **Consumer Price Index**.

Order your copy of the **Market Research Handbook** (Catalogue #63-2240XPB) today for only \$110 in Canada plus \$7.70 GST and applicable PST, US\$132 in the United States, and US\$154 in other countries.

**CALL TOLL-FREE 1-800-267-6677 OR FAX (613)951-1584** and use your VISA or MasterCard.  
**OR MAIL** your order to:

Statistics Canada, Operations and Integration Division,  
Circulation Management, 120 Parkdale Avenue, Ottawa,  
Ontario, K1A 0T6, or contact the nearest Statistics Canada  
Regional Office listed in this publication.

# SERVICES INDICATORS

## For and About Businesses Serving the Business of Canada...

At last, current data and expert analysis on this VITAL sector in one publication!

The services sector now dominates the industrial economies of the world.

Telecommunications, banking, advertising, computers, real estate, engineering and insurance represent an eclectic range of services on which all other economic sectors rely.

Despite their critical economic role, however, it has been hard to find out what's happening in these industries. Extensive and time-consuming efforts have, at best, provided a collection of diverse bits and pieces of information ... an incomplete basis for informed understanding and effective action.

Now, instead of this fragmented picture, ***Services Indicators*** brings you a cohesive whole. An innovative quarterly from Statistics Canada, this publication **breaks new ground**, providing timely updates on performance and developments in:

- **Communications**
- **Finance, Insurance and Real Estate**
- **Business Services**

***Services Indicators*** brings together analytical tables, charts, graphs and commentary in a stimulating and inviting format. From a wide range of key financial indicators including profits, equity, revenues, assets and liabilities, to

trends and analysis of employment, salaries and output – PLUS a probing feature article in every issue, ***Services Indicators*** gives you the complete picture for the first time!

Finally, anyone with a vested interest in the services economy can go to ***Services Indicators*** for **current** information on these industries ... both at-a-glance and in more detail than has ever been available before – all in one unique publication.

If **your** business is serving business in Canada, or if you are involved in financing, supplying, assessing or

actually using these services, ***Services Indicators*** is a turning point – an opportunity to forge into the future armed with the most current insights and knowledge.

Order YOUR subscription to ***Services Indicators*** today!

***Services Indicators*** (catalogue no. 63-0160XPB) is \$112 (plus 7% GST and applicable PST) in Canada, US\$135 in the United States and US\$157 in other countries.

To order, write to Statistics Canada, Operations and Integration Division, Circulation Management, 120 Parkdale Avenue, Ottawa, Ontario K1A 0T6 or contact the nearest Statistics Canada Regional Reference Centre listed in this publication.
